Interurban Electric Railways in some instances have afforded transportation service to territories wholly without facilities before, but in the overwhelming majority of cases the transportation facilities afforded by electric interurban railways have been in addition to the facilities already furnished by steam railroads. The reason for this, of course, is obvious. A steam railroad carrying freight can be built through very long stretches of territory in which there is a sparse population, since it can depend for the bulk of its earnings on its through-freight business. Electric roads are dependent almost entirely on local business, since they cannot compete in cost of service for through business over long distances with steam railroads, even where the steam road has the more circuitous route. The electric road must be built where the population is already fairly thick, and population has developed along the lines of the steam roads. With frequent and cheaper service the electric can compete quite successfully for passenger business with a steam road up to about 25 miles. For a longer haul than this the greater speed of the steam road apparently outweighs the consideration of frequency of service and of lower cost per mile with the great majority of travelers. It was at first believed that electric express service could compete with steam roads between large cities not more than 100 miles apart, but the majority of such electric roads have not been particularly successful. A good instance of this is the Chicago and Milwaukee, which was built at considerable expense with the idea of doing both freight and passenger business, but which went into the hands of a receiver in 1910 and in 1914 was not yet operating at a profit sufficient to pay the interest ordinarily demanded by investors in electric-railway securities on the original cost of its construction.

The influence of electric railways on steam roads which are paralleled is interesting. At first there is a very large falling off of passenger rates on steam roads. The added transportation facilities, however, not only induce more traveling, but add to the attractiveness of residence in the country served by these roads. This induces additional settlement, and after a few years the steam road makes up in long-haul passenger business a part of its loss in local business and in addition gets an inbound and outbound merchandise freight business that in part compensates it for the local passenger business taken away by the electric.

Passenger rates on interurban electric railways vary from three-fourths of a cent to a cent and a half per mile. This compares with two cents to three cents, the prevailing passenger rates on steam roads. Louis Fischer, in

his book on the *Economics of Interurban Railways*, claims that the approximate average earnings of an interurban railway operating from one large town out through a town and village population is about \$10 per capita of intermediate town and village population, regardless of the size, within certain limits, of the primary city terminal. Where the road runs between two large cities, the earnings, in the neighborhood of \$10 per capita of intermediate population, will be . . . by from \$6 to \$20 per capita of . . . of the secondary terminal where this secondary terminal is 40 miles or less away from the primary terminal.

ELECTRIDES, ê-lêk'tri-dêz (Lat., from Gk. ἤλεκτροιdes, *Elektrides*, from ἤλεκτρον, *elektron*, amber). The Amber Islands of Greek mythology, situated at the mouth of the Eridanus, a large river which was identified with the Po, because amber was found at the mouth of the latter. The name was applied also to islands on the northern coast of Europe. See AMBER.

ELECTROBALLISTIC MACHINES. See BALLISTICS.

ELECTROBALLISTICS. The science of measuring the velocity of projectiles by means of electrical instruments. Velocity may be measured, both inside and outside the bore of the gun, at predetermined points in the path of the projectile. The makes and breaks of electric circuits at these points are recorded, as a function of time, by the instrument. See BALLISTICS.

ELECTROCHEMISTRY, GENERAL. The branch of general chemistry that deals with chemical changes producing, or caused by, electrical energy. The growing industrial applications of electrochemistry are making the science itself more and more important every year. Another title of electrochemistry to general interest consists in the fact that the phenomena it deals with have long formed a bond between two great branches of human knowledge—physics and chemistry—the science of the various forms of energy and the science of the various kinds of matter.

The bond may become even more intimate if the comparatively recent hypothesis, according to which electricity itself is a subtle form of matter, turns out to be in agreement with facts. This hypothesis is briefly as follows: Electricity consists of two chemical elements whose atoms, termed "electrons," have exceedingly small (perhaps zero) relative weights; the atoms of positive electricity, or "positive electrons," may be denoted by the symbol \oplus ; the

atoms of negative electricity, or "negative electrons," may be denoted by the symbol \ominus . Like the atoms of hydrogen, electrons of either kind are univalent, so that, e.g., an atom of hydrogen when in the ionic state (i.e., when charged with electricity) is combined with a single positive electron, forming the molecule $\text{H} \oplus$, while an atom of oxygen in that state forms the molecule $\text{O} \ominus$ (just as water is HOH). When not thus combined with the atoms of other elements, electrons may possibly form neutral molecules $\oplus\ominus$. The substance made up of such molecules may have appreciably no weight, may be a nonconductor, and may be capable of electric polarization; and it is worthy of note that these are precisely the properties attributed to the luminiferous ether. While this hypothesis renders Faraday's law (see ELECTRICITY) a special case of Dalton's law of multiple proportions and may certainly be helpful in fixing on the mind a somewhat definite image of the mechanism of electrical processes, it can hardly be said yet to rest on a sufficient foundation. Whether it should be accepted or not will have to be decided on the principle expressed, some years ago, by Poincaré: "It is nonsense to ask of a theory, 'Is it true or false?' The question can only be, 'Is it fruitful or not?'"

At any rate, the electron hypothesis must not be allowed to confuse our conception of *electrical energy* and its relations to other forms of energy. The term "energy," when properly used, designates the cause of any change that is actually taking place, or that is capable of taking place, in a given system. Thus, we may speak of the energy of a falling body, and even of a body suspended at a certain height from the earth's surface; for such a body, if released, *would* fall to the earth. Similarly, we may speak of "electrical energy" whenever a transport of electricity from one point to another is possible in a given system. Energy of every known form can be resolved into two factors—a "capacity factor" and an "intensity factor." In the case of electrical energy the capacity factor is generally known as "quantity of electricity," the intensity factor as "potential difference." Just as in the case of a suspended body the amount of gravitation energy is the greater, the greater the mass of the body and the greater the difference of level between the body and the earth's surface, so in the case of a possible flow of electricity the amount of electrical energy is the greater, the greater the quantity of electricity and the greater the difference of potential between the two given points. Whatever be the ultimate nature of a mass of matter, gravitation energy is still a form of energy. Similarly, whatever be the ultimate nature of a quantity of electricity—whether electricity be a kind of matter or not—electrical energy is still a form of energy, capable of being transformed into kinetic energy, chemical energy, etc.

Electrochemical Reactions. A system in which chemical energy is transformed into electrical is termed a galvanic or voltaic cell, and a combination of two or more cells is termed a galvanic or voltaic battery. One of the first questions that naturally suggest themselves to the student of electrochemistry is, What are the characteristics of those chemical changes whose energy may assume the electrical form? In other words, What chemical reactions can

be utilized for the construction of voltaic cells? The answer is, *All changes, and only such changes, in which acids, bases, or salts take part, or may be caused to take part, can be employed electrochemically.* Substances of these classes are termed "electrolytes," and they are usually employed, in cells, in the form of aqueous solutions, in which their molecules are assumed to be dissociated into fragments, termed "ions" (see DISSOCIATION), that are charged with either positive or negative electricity. In most cells the chemical action consists, on the one hand, in the solution of one of the metallic electrodes, its particles entering the solution in the form of ions, and, on the other hand, in the deposition upon the other electrode of another metal, whose particles formed the ions of the solution. For example, the Daniell cell consists, on the one hand, of a zinc electrode immersed in a solution of zinc sulphate, and, on the other hand, of a copper electrode immersed in a solution of copper sulphate, the two solutions being in contact, and the two metals being connected by a metal wire; the chemical action of the cell consists, on the one hand, in the entrance of zinc into the solutions in the form of zinc ions, and, on the other hand, in the deposition, on the copper electrode, of copper ions in the state of metallic copper. The two simultaneous changes evidently ensue in the system at two separate points connected with each other by a suitable conductor of electricity. This "chemical action at a distance" is an essential characteristic of electrochemical action.

An excellent example of common changes in which electrolytes may be caused to take part, and which may thus be turned into a source of electric energy, is presented by the mere flow of hydrogen or oxygen gas, at constant temperature, from places of higher to places of lower pressure. If, say, hydrogen gas is contained in two separate vessels under unequal pressures, a flow of gas will naturally take place from one vessel into the other if communication is established between them. But the equalization of pressures can also be caused to take place as follows: Let two bars of platinum coated with "platinum black" (finely divided platinum, which has a great capacity for taking up gases) be half immersed in a solution of sulphuric acid, while the other halves are exposed to hydrogen gas contained in two vessels, under two different pressures; on connecting the platinum bars outside the solution by a metal wire, it will be found that a current of electricity passes through the latter, while hydrogen passes through the solution until the pressures in the two vessels have been equalized. The action thus taking place is as follows: in dilute aqueous solution the molecules of sulphuric acid are broken up into electropositive hydrogen ions H and electronegative ions SO_4 ; neutral hydrogen molecules from the vessel of greater pressure enter the solution in the form of hydrogen ions and, replacing the free hydrogen ions of the acid, drive them from the solution in the form of neutral molecules into the vessel of lower pressure. Evidently here, too, as in the case of any other voltaic cell, the electric current is caused by ions taking part in the change.

Electromotive Force. We can now discuss the question as to what determines the electromotive force of a voltaic cell, i.e., the difference

of potential existing between its two electrodes. It was once believed that a considerable difference of potential is established whenever two different metals are placed in contact with each other; but this is now positively known to be wrong. If differences of potential arise from the communication of the electrodes outside the solution, those differences are certainly very small and need not be taken into account. In the case of cells with two different solutions (like the Daniell cell), a difference of potential is known to exist at the surface of contact of the two solutions; but this, too, is comparatively small. The main difference of potential in a cell must therefore be seated at the surfaces of contact between the metallic electrodes and the electrolyte solutions, i.e., at the places where ions form and disappear. But how are differences of potential established there? A clear answer to this question is furnished by modern electrochemical theory. If a liquid is placed in a closed vessel, its vapor gradually attains a maximum pressure which balances the vapor tension of the liquid at the given temperature. Again, if an excess of sugar is placed in some water, the sugar dissolves, or, so to speak, vaporizes into the water, and the portion dissolved gradually attains a maximum "osmotic pressure" which balances the "solution tension" of sugar at the given temperature. Similarly, if a metal is brought in contact with water, its ultimate particles tend to rush into the volume of the water until a maximum osmotic pressure has been attained. Since, according to the theory of electrolytic dissociation, the free particles of a metal in solution are invariably charged with positive electricity, the osmotic pressure of a metal in solution can evidently be exerted only by its electropositive ions. Supposing, now, that a bar of some metal is placed in a solution of *one of its salts*, and remembering that the salt is dissociated into metallic and acidic ions, we readily distinguish three possible cases; viz., the osmotic pressure of the metallic ions may happen to be greater than, less than, or equal to, the maximum osmotic pressure that would balance the "electrolytic solution tension" of the metal.

In the first of these cases some ions will tend to precipitate themselves upon the metal bar, just as some of the vapor of a liquid would tend to condense if its pressure exceeded the vapor tension of the liquid; and the force driving the ions out of solution will evidently be the excess of their osmotic pressure over the solution tension of the metal. As soon, however, as a single ion is precipitated out, the metal bar is rendered electropositive, while the solution is rendered electronegative by the newly created excess of electronegative ions; for before the immersion of the metal bar the electropositive and electronegative ions in solution are precisely equivalent. (See DISSOCIATION.) But this means that a difference of potential will have been created between the metal bar and the solution. Henceforward every electropositive ion driven towards the metal bar by the excessive osmotic pressure will encounter a double force driving it back into solution, viz., the electrostatic repulsion of the positive bar and the electrostatic attraction of the negative solution. Finally, when a certain number of ions have been precipitated out, the double electrostatic counterforce will have become equal to the excess of osmotic pressure,

and then, equilibrium ensuing, the maximum difference of potential possible under the given conditions will have been established between the metal bar and the solution. This will obviously be the greater, the greater the osmotic pressure (i.e., the concentration of ions in the solution), and the less the specific solution tension of the metal.

Passing now to the second of three possible cases, viz., the case in which the osmotic pressure of the metallic ions is less than the specific solution tension of the metal, we see that in this case molecules of the metal will enter the solution in the form of positive ions, rendering the solution electropositive and leaving the metal bar electronegative. In this case, too, an electrostatic counterforce will then come into play, and the difference of potential at the surface of contact will be maximum when this force has become equal to the difference between the solution tension of the metal and the osmotic pressure of ions in the solution. The difference of potential will obviously be the greater, the greater the solution tension of the metal and the less the osmotic pressure of its ions in the solution.

Finally, in the third case, viz., the case in which the osmotic pressure of the metallic ions exactly equals the solution tension of the metal, neither metal will dissolve nor ions precipitate, and consequently no difference of potential will exist at the surface of contact of the metal and the solution.

It may be objected that hypothetical views of this type may and may not be true, and this correctness cannot be expected to be amenable to experimental test. But Palmaer has succeeded in producing, to say the least, strong experimental evidence in their favor. Mercury, viz., is one of those metals whose electrolytic solution tension is very slight, and even in contact with a weak solution of one of its salts it becomes positively charged, mercury ions precipitating themselves upon the metal from the solution. Palmaer placed some metallic mercury in a vessel and covered it with a fairly tall layer of a weak solution of mercury salt. Into this he allowed to run from above a steady stream of droplets of mercury from a dropping funnel. Each droplet took up mercury ions in the upper part of the solution and carried them along, but had to give them up to the lower part of the solution when it joined the body of metallic mercury at the bottom of the vessel, for this body soon became *electropositive* with positive electricity. The lower part of the solution thus becoming positively charged, while the upper part became negatively charged (owing to loss of positive mercury ions), negative ions migrated from the upper part downward, and in this manner a real transportation of the mercury salt as a whole took place. Palmaer was able to show, by actual analysis of different layers of the solution, that the lower layers had become appreciably more concentrated than the upper ones, as was to be expected if the principles developed above were true.

Our principles permit of gaining a clear insight into the mechanism of electrochemical action. Take, e.g., again the Daniell cell, which consists, as we have seen, of a concentrated solution of zinc sulphate and a concentrated solution of copper sulphate, separated from each other by a porous partition, with a bar of metallic zinc in the former solution and a bar of

metallic copper in the latter (see Fig.). It will be seen in a later section of this article that the solution tension of zinc is very great, that of copper very small. Some zinc will therefore enter the solution in the state of positive ions,

DANIELL CELL.

which will render the zinc solution electro-positive and leave the zinc bar electronegative. On the other hand, a number of copper ions will join the copper bar in the state of metallic copper, rendering the bar electropositive and leaving the copper sulphate solution electronegative. Equilibrium will ensue when the excess of solution tension in the case of zinc and the excess of osmotic pressure in the case of copper are exactly counterbalanced by the electrostatic forces as explained above. Now, if we should then connect the two bars by means of a metal wire, a flow of electricity (positive electricity from copper to zinc, negative from zinc to copper) would take place between the two bars, and thus the equilibrium would be destroyed. Freed from the electrostatic attraction, the excessive zinc ions of the zinc sulphate solution would migrate towards the excessive negative ions of the copper sulphate solution. At the same time more zinc, driven by the unchecked solution tension, would go into solution, and more copper ions, driven by the unchecked osmotic pressure, would be precipitated upon the copper bar. If we should break the connection between the bars, the former equilibrium would soon be re-established, and chemical action would cease. But as long as the connection exists, zinc goes into solution, copper is precipitated, and a current of electricity passes through the connecting wire; we say, "electrochemical action is going on."

Suppose, now, that the copper sulphate solution of the Daniell cell were replaced by a solution which could take up molecules from the copper bar, but in which those molecules, instead of being transformed into ions, would form a practically undissociated compound with some other ingredient present. The osmotic pressure of copper ions would thus be extremely slight and might be exceeded by the electrolytic solution tension of copper, in spite of the latter being comparatively small. It is therefore easy to see that under certain conditions it might be possible to reverse the electrochemical process of the cell. As a matter of fact, this is precisely what happens when the copper bar of a Daniell cell is immersed into a concentrated solution of the cyanide of potassium. On closing the circuit copper then goes into solution, zinc is precipitated, and the direction of the current is reversed. This and similar phenomena were formerly described as "anomalous," because they seemed

to contradict the assumption that zinc has a greater "affinity" for acids than copper. Substituting the definite concept "solution tension" for the vague concept "affinity," and adding the factor of the "osmotic pressure of ions," we experience no difficulty in understanding effects like the reversion of current in the Daniell cell by potassium cyanide and many other phenomena. And it must be observed that the osmotic pressure of ions is a measurable quantity (see SOLUTION; DISSOCIATION), and that the solution tension of metals, too, has now been calculated from directly measurable quantities. See further below.

Closely allied to the electrochemical action of voltaic cells is the immediate precipitation of one metal by another. The precipitation of copper by iron from solutions of copper salts, and the precipitation of finely divided ("molecular") silver by zinc, are familiar examples of this phenomenon, the cause of which is almost self-evident in the light of our theory. When a bar of iron, e.g., is immersed in a solution of copper sulphate, the solution tension of the iron causes the appearance of some iron ions, and hence the formation of an excess of positive over negative electricity in the solution; the electrostatic repulsion between the different metallic ions then tends to drive both iron ions and copper ions out of solution; but the solution tension of iron is very great, and so the iron ions remain in solution; on the other hand, the slight solution tension of copper is readily overcome by the force of electrostatic repulsion, and so copper ions are driven out and appear in the state of metallic copper. An analogous exchange takes place when a metal dissolves in an aqueous solution of some acid, the solution tension of hydrogen being overcome by the electrostatic repulsion between the ions of hydrogen and those of the metal. Only here the external pressure of hydrogen gas comes into play; for the electrolytic solution tension of a gas depends upon its pressure, just as its ordinary solubility depends upon the pressure. We have seen above that a voltaic cell may be obtained by using a dilute acid and two quantities of hydrogen gas under different pressures; the two quantities of hydrogen act like two different metals because, owing to difference of pressure, their solution tensions are different. Further, it is easy to see that while for certain pressures of hydrogen the solution tension of a given metal may be greater, for other pressures of hydrogen the solution tension of the metal may, on the contrary, be less, than the solution tension of hydrogen. In other words, if we should place in a vessel filled with hydrogen under sufficient pressure the solution of some metallic salt, the metal might be precipitated out by the hydrogen. As a matter of fact, this curious phenomenon has been observed in the case of several metals. If in a vessel containing hydrogen under a pressure of 18 atmospheres (270 pounds per square inch) metallic zinc is brought into contact with a solution containing per liter 12¾ grams of sulphuric acid and 210 grams of zinc sulphate, no action takes place. If the pressure is slightly diminished, zinc goes into solution, and hydrogen is evolved. In recent years, as set forth in a series of papers published in the *Berichte der deutschen chemischen Gesellschaft*, Ipatieff has investigated this phenomenon in the case of copper and nickel solutions and has succeeded in precipitating copper e.g. in the metallic state

by placing the solution in an atmosphere of highly compressed hydrogen. That the concentration of gas (i.e., the amount compressed in a given volume) plays the determining rôle in this phenomenon is clearly evident; and so this and similar phenomena, too, go to show the inadequacy of older chemical theory, which is *qualitative* (in a vague qualitative way) only the "affinity" factor, and leaving out of account the factor of concentration, "explains" the dissolution of metals in acids by the assumption that metals have greater affinity for acid radicles than hydrogen.

Electrochemical Series. The potential differences established between metals and their salts are now known for a number of different metals. A detailed explanation of the principles on which they are determined would carry us somewhat beyond the scope of this article. Suffice it therefore to state that the starting point is a determination, by an ingenious method, of the potential difference between metallic mercury and solutions of salts, and that the potential difference between mercury and a normal aqueous solution of one of its salts has thus been shown to be 0.99 volt, the metal being electropositive with regard to the solution. This fact known, there is no difficulty in determining the potential difference for any other metal and its solutions. Indeed, let the problem be to determine the potential difference established when metallic zinc is placed in a normal solution of zinc sulphate. To do this, we may construct a cell consisting of a mercury electrode in a normal solution of mercuric sulphate and a zinc electrode in a normal solution of the sulphate of zinc, the two solutions separated by a porous partition and the two metals connected by a wire. By direct determination the electromotive force of this cell may be shown to be 1.514 volts; and as the potential difference between the mercury and its solution amounts to 0.99 volt, it is evident that the potential difference between zinc and the normal solution of its sulphate must be 0.524 volt. In this calculation the slight potential difference between the two solutions has been neglected. In calculating the following table, however, that difference, too, has been taken into account; and so the figure for zinc, 0.51, is somewhat more precise than our figure, 0.524. The table shows the potential differences between metals and their salt solutions of normal concentration, the plus sign showing that the solution is electropositive with regard to its metal, and the minus sign showing that the solution is electronegative with regard to its metal.

Magnesium ...	+1.22	Iron.....	+0.06	Copper	0.60
Zinc	+0.51	Nickel	0.02	Mercury	0.99
Aluminium ..	+0.22	Lead	0.10	Silver	1.01
Cadmium....	+0.19	Hydrogen ..	0.25		

The series is similar to part of the old electrochemical order of Berzelius. (See historical section under CHEMISTRY.) Only, again, while that order was purely qualitative, the modern series represents an exact qualitative expression of the electrical properties of metals and besides refers to a definite concentration of their solutions. Since the potential difference between a metal and a solution depends upon the solution tension of the metal and the osmotic pressure of its ions in the solution, and since both the potential difference and the osmotic pressure can be deter-

mined, it is evidently possible to find also the solution tensions. The following table shows the results of such calculations based on the table given above:

Magnesium....	10 ¹⁴	Iron	10 ⁸	Copper.....	10 ⁻¹²
Zinc	10 ¹³	Nickel.....	10 ⁹	Mercury.....	10 ⁻¹⁵
Aluminium ..	10 ¹³	Lead	10 ⁻²	Silver	10 ⁻¹⁵
Cadmium	10 ⁷	Hydrogen	10 ⁻⁴		

The figures represent the solution tensions in terms of atmospheres and may be changed to pounds per square inch by multiplying by 15. The solution tension of iron, e.g., equals a pressure of 15,000 pounds per square inch. The enormous tension of magnesium may serve to indicate how great may be the electrostatic counterforces long before the amount of metal in solution has become appreciable.

Concentration Cells. We have seen, in a previous section, that in the usual electrochemical cell the main seat of electromotive force is at the surfaces of contact of the metallic electrodes and the solution. There are, however, cells in which the electrodes may be of one and the same metal; if in such a cell the solution in contact with the two electrodes were also the same, the two electrodes would be *equally* charged, and there would obviously be no difference of potential between them; in other words, such a cell would possess no electromotive force at all. But since, as we have seen, the electrification of a metal depends on the concentration of the solution in contact with it, two electrodes made of one and the same metal may be differently electrified by placing them in contact with solutions of different concentration. This suggests the idea that a cell may be constructed by preparing two unequally strong solutions of one and the same electrolyte, placing them in compartments separated by a porous partition (of, say, unglazed porcelain), and immersing two bars of some metal in the two solutions. And, as a matter of fact, if the electrodes of such a cell are connected by a metal wire, a current of electricity is found to flow from one to the other. In such a cell the seat of potential difference is at the surface of contact of the two unequally strong solutions, and therefore such a cell is called a "concentration cell."

Nernst has shown how the electromotive force of a concentration cell may be predetermined theoretically. To take the simple case of an electrolyte made up of two ions, like hydrochloric acid or potassium chloride, the electromotive force, according to Nernst, is proportional to the logarithm of the ratio of the two concentrations employed (or, more precisely, the ratio of the *ionized portions* of the electrolyte in the two unequally strong solutions employed). Calling the concentration of the ionized electrolyte in the stronger solution η_1 and the concentration of the ionized electrolyte in the weaker solution η_2 , the electromotive force of the cell, no matter what metal is used to make the electrodes (as long as the two electrodes are identical), may be calculated by the formula:

$$E = C \cdot \log \frac{\eta_1}{\eta_2}$$

In this formula E denotes the electromotive force. The factor C may be calculated theoretically by multiplying T (the absolute temperature) by 0.0000861 (the so-called "gas constant")

in C. G. S. units for a quantity of substance carrying one C. G. S. unit of electricity), and further multiplying the product by the quantity $\frac{u-v}{u+v}$, where u and v are the conductances, i.e., the capacities for carrying electricity, of the two ions involved. Obviously, if the two conductances u and v should happen to be equal, we should have $u-v=0$; therefore, $C=0$; and therefore, according to the above formula, $E=0$. This shows that the electromotive force of a concentration cell is due to the ions being unequally mobile, and if in a given case the two ions of an electrolyte should happen to be capable of traveling (diffusing) with the same speed, then a difference of concentration in different parts of a solution will produce no electromotive force. Generally, for a given ratio of concentrations the electromotive force will be the greater, the greater the difference of the conductances of the two ions. As an example, the conductance of a hydrogen ion at 18° C. (291° on the absolute scale) is expressed by the number 318; the conductance of a chlorine ion by the number 65.9. If we should now fill a porous porcelain cell with $\frac{1}{10}$ -normal hydrochloric acid, and place the cell in a beaker containing hydrochloric acid 10 times as strong ($\frac{1}{10}$ -normal), then $\eta_1/\eta_2=10$, and, according to the above formula, we should get $E=0.0379$, a considerable electromotive force. If we should next employ potassium chloride instead of hydrochloric acid, the concentrations being the same as before, we should have to expect a *very small* electromotive force; for the conductance of the potassium ion (65.3) is nearly the same as that of the chlorine ion (65.9). As a matter of fact, the electromotive force of such a potassium chloride concentration cell is less than three ten-thousandths of a volt,—nearly 150 times less than the electromotive force of the corresponding hydrochloric acid cell. In connection with this subject it would be well to read also the article *DIFFUSION*.

Electrolysis. The electrochemical principles developed above, together with the theory of electrolytic dissociation (see *DISSOCIATION*), explain the mechanism of electrolysis without any difficulty. We have seen above that in a voltaic cell chemical changes are used to produce electrical energy; in electrolysis, on the contrary, an electric current from some outside source is passed through the given system and causes chemical changes to take place in it. The laws of electrolysis may be found stated in the article *ELECTRICITY*.

Transformation of Energy. The term "chemical affinity" is now often used, not only in connection with compounds, but also in connection with their transformations. It is a fundamental principle in modern exact science, that any change whatever that takes place in a given system without the supply of energy from without is capable of yielding mechanical work. Thus, a weight can be lifted by the expansion of a sufficiently compressed gas, and of course the greater the weight, the greater the work done. The greater the work done, the more the gas is cooled; for the work is done at the expense of the energy of the gas. If the same gas were allowed to expand the same amount in vacuo (i.e., without having to overcome any resistance), no work would be done, and therefore no fall of temperature would be observed; in other words, the total energy of the gas would remain un-

changed; yet its capacity for doing work would obviously be diminished owing to the diminution of pressure. Physicists therefore distinguish between the total energy of systems and their free energy, the latter representing that part of the total energy which can be transformed into mechanical work when the system undergoes a spontaneous change. Evidently the maximum work that can thus be obtained measures the free energy of the system; and as the free energy represents the "driving power" that causes the change, it is evident that we have obtained an exact measure of that cause when we have measured the maximum work that can be yielded by the change. In the case of chemical transformations it is that same "driving power" which is now often referred to as the "chemical affinity of reactions." In the case of voltaic cells the free chemical energy may be entirely transformed into electrical energy. If the cell is perfect, i.e., if it yields really the maximum of electrical energy that can be obtained from its chemical changes, then evidently the electrical energy measures the affinity of the chemical changes; for the electrical energy of a cell can be entirely transformed into mechanical work. Now, we have seen in the introductory section of this article that electrical energy is a product of two factors, quantity of electricity and potential difference. The quantity of electricity passing through a cell is proportional to the number of chemical equivalents of the ions entering or leaving the solution (Faraday's law), each chemical equivalent (in grams) carrying 96,540 coulombs of electricity. On the other hand, the total potential difference of a cell is measured by its electromotive force and can be readily determined by the use of some "standard" cell. It is therefore clear that the electrical energy of an electrochemical process can be readily ascertained, and that the chemical affinity of any reaction in which acids, bases, or salts can be caused to take part is proportional to, and hence is measured by, the electromotive force of a voltaic cell based on the reaction. It is further clear that, on the contrary, whenever the maximum mechanical work that can be yielded by a given transformation can be ascertained without the aid of an electric process, the electromotive force of a cell based on the transformation can be calculated beforehand.

One more important point claims attention before we dismiss the subject of the energy changes of voltaic cells. The chemical reactions of a cell can also take place without producing electrical energy. Thus, the reaction of a Daniell cell can be produced by simply immersing a bar of zinc into a solution of copper sulphate. In that case the change is accompanied by the evolution of a definite amount of heat. The question therefore arises, Can all that "heat of the reaction" be transformed into electrical energy or not? At one time this question was answered in the affirmative ("Thomson's law"). But Willard Gibbs and Helmholtz have proved thermodynamically, and it has since been demonstrated experimentally, that the electrical energy of a cell need not by any means equal the heat of the reaction; that, on the contrary, the latter is usually greater than the former, so that even in perfect cells (producing a maximum of electrical energy) a rise of temperature might generally be observed. In certain rarer cases, on the contrary, the electrical energy produced in a cell is, curiously enough, *greater* than the

total heat energy of the reaction. Not, of course, that the excess of electrical energy is created by the cell out of nothing, but in addition to the heat of the reaction, a certain amount of energy is abstracted from the surroundings, and, as a rule, the temperature of such a cell falls during action. As a rough approximation, however, "Thomson's law" is still useful for practical purposes. See THERMOCHEMISTRY.

History. The earliest electrochemical observation on record was made by Deimann and Paets van Troostwyk, of Haarlem, in 1789. The experiment was carried out as follows: A glass tube with one end closed and the other open, and with a metal wire sealed into the closed end, was filled with water and inverted over a dish of water; a second metal wire was passed through the open end of the tube, up to within some distance of the end of the upper wire; and electric sparks were caused to pass between the ends of the two wires. The result was that water was decomposed into its constituents, oxygen and hydrogen, a mixture of which collected in the upper part of the tube. As long as the end of the upper electrode remained immersed in water, nothing further happened; but the instant the end of the electrode became exposed to the mixture, a violent explosion took place, owing to the recombination of the two elements. In a similar manner Ritter afterward carried out the first true electrolysis, using silver wires as electrodes and a solution of a silver salt as the electrolyte. Then came Volta's celebrated experiments, which resulted in his invention of voltaic batteries (see VOLTAIC BATTERY); and in 1795 Volta was able to prepare the first electrochemical series. An appreciation of the work of Davy and Berzelius, and of the sway of Berzelius' ideas exercised for many years in the science of chemistry, may be found in the article CHEMISTRY (historical section). Faraday's discovery, in 1834, of the true laws of electrolysis marked a great step forward both in chemistry and in the science of electricity. The conception of energy, of its several forms, and of their mutual transformations, was developed in course of the fifth and sixth decades of the nineteenth century, and in 1847 Helmholtz first advanced the belief that the heat of the chemical reactions of a cell may be entirely transformed into electrical energy. Having been again brought forward by Thomson in 1851, the belief became known in science as "Thomson's law." The researches establishing the true relation were carried out by Gibbs in 1878 and by Helmholtz in 1882 and were completed by the experimental investigations of Czapski and Jahn. In 1886 Van't Hoff introduced the modern theory of osmotic pressure (see SOLUTION), and in 1887 Arrhenius advanced the theory of electrolytic dissociation (see DISSOCIATION), which is at the basis of the most important chapters of modern electrochemistry. The idea that electrolytes must be more or less broken up in their solutions originated with Clausius; but Arrhenius was the first to give it its present quantitative form, to connect it with the theory of solutions, and to demonstrate its great importance for theoretical chemistry. The researches of Hittorf on the relative rates of migration of the ions during electrolysis were carried out as early as 1853 to 1859, but gained great scientific importance only after Arrhenius established his theory of dissociation. Other important names connected

with the progress of general electrochemistry are those of Ostwald, Nernst, Planck, Le Blanc, and Kohlrausch, Nernst especially being well known for his theory of the cell, of which a partial sketch is given above under the side head *Concentration Cells*. The concept of electrons originated in Helmholtz's lectures on Faraday's ideas of electricity, delivered in London in 1881. Among those who have contributed to the recent development of this promising idea are Nernst, Abegg, and Bodländer.

ELECTROCHEMISTRY, INDUSTRIAL. Electrochemical processes are now employed in extracting metals from their ores and in parting them from their alloys; in the deposition of certain of the finer metals upon the surfaces of baser metals and other materials; in the manufacture of various chemical products employed in the arts and for various miscellaneous purposes. The processes of *electrometallurgy*, by which metals are extracted from these ores or parted from these alloys, can be best considered in the articles describing those metals.

The electrodeposition of certain metals upon the surfaces of other substances is called *electroplating*. When electroplating is employed as a means of copying printing type, medals, seals, woodcuts, etc., it is called *electrotyping*. The metals commonly used for electroplating other metals are copper, nickel, silver, and gold, which are in each case made the anode or positive pole of a voltaic current, while the metal to be coated is made the cathode or negative pole. The electrolyte or immersing bath is differently composed, according to the metal which is to be deposited.

Electrically deposited copper is now largely used to protect and ornament architectural ironwork, the coating varying from 8 to 10 ounces per square foot for smooth plates, to 14 to 16 ounces for rough cast iron. For interior ornament electrobronzing is often employed, using a coating of from 2 to 3 ounces per square foot. In Europe it is common practice not to deposit the plating directly on the iron, but on a suitably prepared varnish, thus avoiding the necessity of cleaning, but at the same time giving a plating which is easily knocked off; in the United States the iron is very carefully cleaned and the copper deposited directly upon it, and so firmly that the original metal with its coating may be bent or twisted without rupturing the plating.

In the electrodeposition of nickel, or nickel

plating, the bath consists of nickel-ammonium sulphate dissolved in boiling water. The articles to be plated are first cleaned with abrasives or acids and after the plating is finished are polished. Gold and silver plating are employed in making jewelry, ornaments, and tableware of all descriptions. In silver plating the bath used is a solution of chloride of silver, cyanide of potash, and water. In gold plating either a hot or a cold solution may be used, and each is variously compounded, according to the result which it is desired to obtain. After the plating has been deposited the article is suitably burnished. The deposition of copper in electrotyping is one of the most important applications of electrochemistry and plays an important part in printing, under which title it is described. See ELECTROPLATING; PRINTING.

Electric Furnace. In the electric furnace there is not, as a rule, any electrolytic decomposition or electrolysis proper, but merely an extremely high temperature caused by the passage of the current . . . offering resistance. Thus, . . . production of the *Carbides*, by the action of the high temperature, a mixture of silica (sand), sodium chloride (salt), and coke silicon carbide (carborundum) is obtained. Similarly, by the action of the high heat on limestone, coke, and a flux, we obtain calcium carbide, from which acetylene gas is produced. The thermoelectric production of phosphorus has now replaced the older methods. Calcium phosphate is mixed with charcoal and sand and heated in the electric furnace, when the phosphorus liberated is distilled off in a current of coal gas. Artificial graphite is also made in connection with the manufacture of carborundum by volatilizing all but the carbon at still higher temperatures. See ELECTRIC FURNACE.

In the production of chemical compounds by electrical action we may mention, first, the electrolysis of alkaline chlorides. If the chloride, as sodium chloride (salt), is in the fused state, as in the Acker process, we obtain metallic sodium and chlorine. By a secondary reaction, that of steam on the sodium-lead alloy first obtained in this process, solid caustic soda is obtained, while the liberated chlorine is used to produce chlorinated lime or bleaching powder. If the chloride is in solution, as in brine, we may, by using a diaphragm, obtain caustic soda solution and chlorine at the two electrodes, or when no diaphragm is used, we may obtain as the sole product of the electrolysis an alkaline hypochlorite or a chlorate, according to conditions of temperature. The production of hypochlorite solution is now largely made use of for bleaching in textile works and in the paper industry. The production of chlorates electrolytically has largely replaced the older methods. (See SODIUM.) The decomposition of fused alkaline hydroxides is also practiced, as in the production of metallic sodium, by the Castner process, and latterly the production of metallic magnesium and calcium. Aluminium is produced in the Hall process by the electrolysis of aluminium oxide in a bath of fused cryolite. A number of organic chemical compounds are also produced at present by the aid of electrolysis. Chloroform and iodoform are thus made by the action of nascent electrolytic chlorine or iodine upon alcohol or acetone. Chloral is also a product of a similar action. A number of organic dyes are also produced with the aid of electro-

lytic action, either by oxidation or reduction. Among the lesser applications of electrochemistry may be mentioned the purification of sewage, the tanning of hides, the aging of wines, the production of ozone, the fixation of atmospheric nitrogen and manufacture of nitric acid, and the preparation of carbon disulphide.

ELECTROCULTURE OF PLANTS. The culture of plants under electric stimulus. It has long been known that plants respond to electric stimuli, and many investigations have been made to ascertain practical means of realizing the benefits of this force. The subject naturally divides itself into the direct use of the current when applied to the seed, plant, or soil, and the use of the electric light. The Abbé Nollet seems to have been one of the first to notice that the germination of seeds could be hastened by electrifying them before planting, and Bertholon carried on extensive experiments on electric stimulation of plants in 1783. Later, Speenew stimulated for a few minutes moist seed of beans, peas, barley, and sunflower, after which they were planted. Such seed germinated in half the time required for untreated seed. His experiments were repeated at the Massachusetts Experiment Station, where the germination was accelerated and the total germinations increased. Direct experiments upon the growth of plants have been made, in which zinc and copper plates, connected by wires, were placed in the soil in which the plants were grown, or wires were run through the soil and connected with a battery or electric machine of some sort. The first method has been successfully tried in England and Germany, with the result that larger crops of peas, barley, and grass were obtained from electrified plots of ground. The second method has been tried many times, the experiments of Warner at the Massachusetts Experiment Station being of this class. In 1893 he grew parsnips, lettuce, carrots, turnips, beets, salsify, onions, peas, and tomatoes. The seed of most varieties germinated sooner, developed better, and the tomatoes ripened earlier, where the soil was subjected to the electric current. The nearer the plants were to the electrodes, the better was the growth. More recently Stone, at the same experiment station, found that greater stimulation was secured by increasing the electric tension of the atmosphere than by passing the current through the soil. Alternating electric currents appear superior to direct currents for stimulating plants. Various forms of accumulators of atmospheric electricity have

been tried with greater or less success. That atmospheric electricity influences growth is shown by the experiments of Grandeau, who grew maize inside an insulated cage. The stalks were much smaller than those receiving the effect of the electricity of the air. The effect or advantage secured is explained by the fact that the electric current induces more rapid changes in the seed and soil, or that electrified plants are enabled to take up carbon dioxide more rapidly owing to the treatment. Lemström in Finland tried a special electric machine connected with a system of overhead wires, and while the apparatus was faulty an increase in the production of various crops was shown. Priestly, in 1910, gave an account of experiments carried on in England and Scotland by Sir Oliver Lodge, J. E. Newman, and others, in which the effect of overhead discharges of electricity on plants was studied. Installations were made in greenhouses and open fields, and earlier and more productive yields are reported for wheat, barley, cabbage, tomatoes, beets, carrots, and strawberries when stimulated by the discharge. These results seem to have been confirmed in Germany and France. Experiments by the United States Department of Agriculture have shown gains, but not sufficient to indicate that electroculture is commercially profitable.

The effect of the electric light has been very fully investigated at the experiment stations of Cornell University and West Virginia, the arc light being used at the former station and the incandescent lamp at the latter. In the case of plants grown under the electric light the effect seems to be exerted through the hastening and prolonging of the assimilation of the plants. A large number of vegetable and flower and foliage plants have been experimented upon. In the experiments with the arc light it was soon found that the naked light exerted an injurious effect upon many plants. This is believed to be due to the presence of ultra-violet rays, the spectrum of the electric light being unlike that of sunlight. A glass screen, as an ordinary globe, was found to cut out the injurious rays and to allow the beneficial rays to pass through. Hanging an arc light above a greenhouse had the same effect. By this method the flowering period of many plants was in some cases hastened, as with Easter lilies, being advanced as much as 10 days, and the colors were more intense. With vegetables the best results were secured with lettuce, plants of which were forced a week or more in advance of those in the unlighted portions of the house. This fact has been taken advantage of in a number of instances in the commercial forcing of lettuce. Similar results were obtained with the incandescent light at the West Virginia Experiment Station. The light from the mercury-vapor lamp, especially when quartz tubes are used, seems to be detrimental to plant activities.

The practical utilization of the electric light in horticulture seems at present limited to forcing lettuce and flowers. With these illumination for a month until midnight seems to give results commensurate with the expense. The whole subject is hardly beyond the experimental stage as yet, except as noted above. See **ELECTROTAXIS**; **ELECTROTROPISM**; **GERMINATION**.

ELECTROCUTION (from Gk. *ἤλεκτρον*, *ēlektron*, amber, electricity; a barbarous formation on the analogy of *execution*). A method of inflicting the death penalty by passing through

the body of the doomed criminal a current of electricity. It represents the latest attempt to rob the infliction of the death penalty of the revolting features of the prevalent mode of execution by hanging. While not entirely successful in this aim, it has in some parts of the United States been accepted as a more humane method of capital punishment than that which it is aimed to supersede. It has been adopted in New York, New Jersey, Pennsylvania, Massachusetts, Ohio, Indiana, Nebraska, Kentucky, North Carolina, South Carolina, Virginia, and Arkansas. The legislation which put it into effect in New York was based upon the recommendation of a commission appointed "to investigate and report to the Legislature the most humane and approved method of carrying into effect the sentence of death in capital cases." Notwithstanding the eminence of the commissioners, the prolonged and careful investigation which they gave to the subject, and the deliberate and cautious conduct of the Legislature in dealing with the report, the statute adopted for the purpose of giving effect to the conclusion of the commission, and changing the mode of executing the death sentence from hanging to electrocution, was assailed as unconstitutional, on the ground that it provided for the infliction of a cruel and unusual punishment. This contention was not sustained by the courts. On the contrary, they agreed with the commission that the application of electricity to the vital parts of the human body, under the conditions and in the manner contemplated by the statute, must result in instantaneous and painless death, and therefore would be a far more humane method of inflicting the death penalty than that by hanging. Consult *People ex rel. Kemmler v. Durston*, (119 New York Reports, 557, 1890), and 41 *Albany Law Journal* (242, 361, 382, 425, 489, 1890). See **PUNISHMENT**, and the authorities there referred to.

ELECTROLYSIS. For theoretical discussion, see **ELECTRICITY**; **ELECTROCHEMISTRY**, **GENERAL**.

ELECTROLYSIS OF GAS AND WATER MAINS (from Gk. *ἤλεκτρον*, *ēlektron*, amber + *λύσις*, *lysis*, dissolution, from *λύειν*, *lyein*, to loose). The eating away or disintegrating of the metal, caused by stray electrical currents. Electric street-railway systems are chiefly responsible for this action, through the lack of proper facilities for the return currents from the car motors to the power house. The softening or pitting of the pipes takes place where the current leaves them, particularly at joints, where the electrical resistance of the metal is greater than that of the surrounding earth. The danger from this source was so little realized in the early days of electric street railways that direct electrical connection was sometimes made with gas or water mains. Since about 1892 the problem has been assuming more and more serious proportions, and there have been numerous papers and discussions on this subject at the meetings of the various water works and gas associations. At the points of departure of these stray currents, whether permanent or temporary, the metal, be it iron, steel, or lead, is liable to become so badly decomposed as to be in serious danger of giving way. This is particularly true of water mains, which are under very many times as much pressure as gas mains. When water mains are thus broken, great damage may be done by the escaping

water, and a city or portion of a city might be at the mercy of the flames if a fire should break out. If, instead of the mains, the service pipes or house connections give way, the danger and inconvenience are not so great, but no end of trouble and much needless expense are often caused. Where gas mains fail, the ground becomes more or less permeated with gas, and if the latter has an opportunity to accumulate, an explosion may occur. Since 1890 water-works managers have had more and more trouble with electrolysis, and in several instances have felt compelled to sue street-railway corporations for damages and to ask the courts to enjoin the trolley companies from a continuance of the conditions which give rise to so much anxiety, expense, and danger. The final decisions of the courts have in all cases, however, held the railway companies blameless, provided the latter used all reasonable means to reduce the electrolytic action. It should be understood that the rails of the trolley lines are injured where the current leaves them, and that these imperfections in the circuit increase the power required to operate the railways. The remedy for the evil is to provide ample and unfailing means for the return of the current to the power house. Much can be effected, in the case of the ordinary single-wire overhead trolley, by a thorough bonding of the rails; but the consensus of opinion among water-works officials is that this is insufficient or unreliable, and that either the double overhead-trolley system or an underground return wire should be provided. Consult the *Journal of the New England Water-Works Association*, and the *Proceedings of the American Water-Works Association* for professional and technical papers on this subject, as well as a report from the Committee on Electrolysis to the American Electric Railway Association (1913), and Rosa and McCollum, *Technologic Paper No. 27, United States Bureau of Standards*, and other publications of the bureau.

ELECTROMETER (from Gk. *ἤλεκτρον*, *ēlektron*, amber + *μέτρον*, *metron*, measure). An instrument for measuring the difference of electrostatic potential between two charged conductors. The electroscope (q.v.) and the torsion balance (q.v.) are forms of electrometers and can be used to indicate the amount of electricity with which a given conductor is charged; but there are finer and more accurate instruments which are also based on the attraction and repulsion of two charged conductors. In the Peltier electrometer a thin vane of aluminium has attached to it a small magnet, whose magnetic moment is known, and which, being suspended at a point where the intensity of the earth's magnetism has been ascertained, enables us to determine the amount of any force which deflects it. There is a similar fixed arm which is charged with electricity of one kind, while the first vein is charged with electricity of the same kind. Consequently there is a repulsive action between the two, whose extent depends upon the charges which the two conductors have. The capacity of these conductors is always the same;

consequently the amount of electricity with which they are charged must depend upon the difference of potential; and this rule holds good in most forms of electrometers. A more accurate form of electrometer consists in balancing the mutual attraction of two charged plates by weights. A charged disk with a plain surface is attached to one arm of a balance, but electrically insulated from its metallic parts. By means of balancing weights or the movement of the arm of the balance, the strength of attraction can be determined. This device, which was invented originally by Snow Harris, was later improved by Lord Kelvin and was an instrument quite delicate in its action. In Lord Kelvin's hands it furnished valuable results and was known as an absolute electrometer. He also devised the quadrant electrometer, where there is a needle of thin aluminium suspended over four quadrants which are connected in pairs. A charge of electricity is communicated

QUADRANT ELECTROMETER.

to one pair of quadrants diametrically opposite each other, and a charge of the opposite kind is given to the other pair, or they are connected with the earth. The needle, therefore, will be attracted by one set of quadrants and repelled by the other, the amount of deflection measuring the potential difference to which the quadrants are charged. The action of the apparatus will be understood on reference to the illustration. Here the needle is charged by an electrophorus or is in contact with a Leyden jar, and the two sets of quadrants are charged to the difference of potential which it is desired to measure. The amount of deflection can be determined accurately by using a reflecting mirror on the needle and a telescope and scale, as is done with

LORD KELVIN ELECTROMETER.

the galvanometer (q.v.), and it is possible to measure even such small differences of potential as those of the two elements of a cell. The form of electrometer illustrated is supplied with a replenisher in the shape of a small Leyden

jar at its base, and the quadrants are made double, or box shape, to increase the effect. In the electrostatic voltmeter used in the measuring of alternating currents a vane of aluminium is delicately pivoted, so that it may revolve between two brass plates from which it is insulated. The vane is connected with one conductor from the alternator, or other source of current, while the other conductor is connected with the fixed brass plates. When the vane and the plates are charged, there is a repulsive action between them, and the vane is revolved. The pointer attached to one arm moves over a graduated scale, indicating the difference of potential, and counterweights of different amounts may be placed on the lower arm so that the range of the instrument can be varied and several sets of readings for different ranges of potential obtained. By increasing the number of vanes and fixed plates the sensitiveness of the instrument is increased, and it is then termed a multicellular voltmeter. In the study of radioactivity quadrant electrometers of very small size, and therefore small electrical capacity, are used where the needle is made of paper, aluminium foil, or silvered mica, suspended by a quartz fibre or very fine phosphor bronze strip, and so light that no damping beyond air friction is required. With a fine fibre the sensitiveness may be as great as a scale division for a potential difference between the quadrants of $\frac{1}{10,000}$ of a volt, so that currents can be measured far smaller than with the best galvanometer. The capillary electrometer of Lippman and Dewar, used to measure small differences of potential, consists of a glass tube placed horizontally, with its ends turned up and filled with dilute acid. At the middle of this tube is placed a drop of mercury, and as the current passes through the acid the drop travels along the tube towards the negative pole. This action is due to a change in the surface tension between the mercury and the acid, caused by the liberation of gas. Other electrometers figure mostly in experiments in static electricity and for accurate determinations requiring careful manipulation. See TERRESTRIAL ELECTRICITY.

ELECTROMOTIVE FORCE. See ELECTRICITY, *Electrokinetics*; *American Handbook for Electrical Engineers*, ed. by Pender (New York, 1914); also ELECTROCHEMISTRY, GENERAL.

ELECTRON. A particle of matter, charged with negative electricity, having a mass about $\frac{1}{1836}$ part of that of the hydrogen atom, probably a common constituent of the atoms of all chemical elements. The electron hypothesis assumes that the charge on an electron is the natural unit or atom of negative electricity, and that the existence of a negative charge on a body results only from the congregation there of electrons.

The recognition of the separate existence of particles of mass smaller than that of the hydrogen atom is due to Sir William Crookes, who took the position that the luminous streams ("cathode rays") that proceed from the cathodes of highly exhausted vacuum tubes are composed of tiny material particles moving away from the cathode like a storm of pro-

jectiles. He did not definitely commit himself to any theory as to the precise nature of these particles, but recognized them as being somehow different from the ordinary molecules of matter and maintained that the cathode rays presented "a new or fourth state" of matter. His views, though opposed strenuously at first by competent authorities, have been substantiated and extended by subsequent experiments.

J. J. Thomson, in 1897, succeeded in completely demonstrating the general correctness of Crookes's hypothesis and in defining very closely the nature of the rays. He found that they consisted of negatively charged particles, moving with velocities varying between 20,000 and 50,000 miles per second, and that the mass of these particles was about $\frac{1}{1836}$ that of the hydrogen atom. He also showed that electrons of the same small mass could be produced in a variety of ways. They are emitted from a metal plate exposed to ultra-violet light, from the surface of glowing metals, from the electric arc, and from flames. In all these cases an external stimulus and supply of energy is necessary to free the electron, but it is found that the radioactive substances, radium, thorium, uranium, etc., spontaneously and continuously emit these small, negatively charged particles with a wide range of velocities, in some cases $\frac{1}{10}$ that of light. The charge on the electron in all these cases is found to be the same and equal to 4.77×10^{-10} electrostatic units. It has been shown that the charge carried by the electron or a gaseous ion is the same as that on a monovalent ion in electrolysis, and it thus seems to be a natural and indivisible unit of electricity.

The constancy of the charge and the mass of the electron, whatever its origin, naturally led to the view that all matter contained this primordial element. The conception of an atom consisting of a number of mobile negative electrons embedded in a sphere of positive electrification was embodied by Lord Kelvin in a paper called "Aepinus Atomized." This electronic model has been further developed by J. J. Thomson, who has investigated the properties of model atoms, consisting of a large number of rapidly revolving electrons held in equilibrium by these mutual repulsions and the forces due to a fixed distribution of positive electricity. He has shown that such systems imitate strikingly many of the most fundamental properties of chemical atoms.

Such an atom furnishes a ready means of explaining the mechanism by which the radiation of the electromagnetic waves of light by matter is effected. These charged particles within the atom radiate no energy unless subjected to an acceleration; but if one is displaced from its position of equilibrium, it will vibrate about its mean position of rest and radiate electromagnetic energy into space until brought to rest. From this view of the origin of radiation Lorentz pointed out that, if a source of light were subjected to an intense magnetic field, it was to be expected that the lines of the spectrum should be broadened, and this prediction was later experimentally verified by Zeeman, who found that the spectrum lines were not only spread out, but completely split up into three or more lines. Measuring the distance between these lines, it may be shown that the ratio of the charge to the mass of the vibrating particles to whose disturbance the lines are due is the same as the ratio for the electron as reached by other methods.

The problem of the conduction of electricity along metal conductors has also been attacked on the same ground by Thomson and Drude. On the electronic theory all conductors are supposed to contain a large number of free negative electrons which can pass freely between the atoms of matter. These electrons are considered as moving freely to and fro in the spaces between the molecules of the metal. Under the influence of an electric field the electrons are set in motion and act as the carriers of the current, the positive carriers remaining either immobile or moving very slowly.

The nature of the electron, whether it is a fragment of an atom of matter or a disembodied electric charge, so that all its properties can be accounted for by purely electrical theory, has been somewhat elucidated by the following considerations. A moving charge behaves like an electric current and produces a magnetic field about it. Electromagnetic energy therefore is stored up in the medium and travels with the moving charge, and the amount of this energy is proportional to the square of the speed for speeds small in comparison to the velocity of light; but when a mass is set in motion, it possesses kinetic energy proportional to the second power of its speed. As work is done when the speed of a mass is changed, so it must be done when the speed of an electric charge is changed; therefore an electric charge possesses inertia or mass, the fundamental property of matter. It will tend to resist any acceleration. If we consider a charged body, its inertia or mass is due partly to the neutral body and partly to the charge on it.

In experiments by Kaufmann to determine how far the mass of the electron results from the charge associated with it, radium was used as a source of electrons, as it expels electrons with a wide range of velocities, some being as high as .9995 that of light. By an ingenious experiment Kaufmann determined the mass of the electron at different speeds, found that it increased rapidly as the velocity of light was approached, and, by comparison of theory with experiment, showed that the mass of the electron was purely electrical in origin. It is therefore probable that it is a disembodied charge, possessing, however, the characteristic property of mass in virtue of its charge.

ELECTROPH'ORUS (Neo-Lat., from Gk. ἤλεκτρον, *ēlektron*, amber + -φορος, -*phoros*, bearing, from φέρειν, *pherein*, to bear). This apparatus consists of a circular disk of hard rubber, vulcanite, shellac, or other insulating material on a metallic surface or form, and a movable metal cover with an insulating handle. The disk is first negatively electrified by being struck briskly with a foxtail or catskin, and then the metal cover is placed on it. The next step is to touch the cover with the finger, which may produce a slight spark, and then grasping the insulating handle to raise it, keeping it parallel to the surface of the disk. If presented to the finger or any body in contact with the ground,

a spark will ensue, and this can be secured for a number of times by simply placing the cover on the disk, touching it with the finger, and removing. This process can be repeated until the disk loses its charge by leakage into the air. The action of the electrophorus depends upon induction and the underlying principle is the same as in the electrical machine and other electrical apparatus. When the vulcanite or shellac is rubbed, it is negatively charged, the charge residing somewhat below the surface. Now, when the cover is put on, the negative charge of the disk acts on the plate inductively, attracting the positive electricity to the lower side and repelling the negative to the upper side. When the finger is brought into contact with the metal, it affords an opportunity for this negative electricity to escape to the ground and leaves the cover with a positive charge which is held bound. Raising the cover now positively charged and bringing it near some object in connection with the ground, we have a sharp spark as the equilibrium is restored and the plate discharged. The electrophorus can be used to charge bodies and perform a number of experiments in frictional electricity. See ELECTRICITY.

ELECTROPHORUS.

ELECTROPLATING. A process by means of which salts of gold, silver, platinum, nickel, copper, or other costly metals are decomposed by an electric current, a coating of metal being deposited on the surface of objects made of some cheaper metal. In 1838 Jacobi, of St. Petersburg, published a description of a method capable of reproducing any line engraved on copper into a relief by galvanic process. Soon after Thomas Spencer, of Liverpool, independently announced his discovery of a similar process. From these discoveries have grown the extensive electroplating processes that include the deposition of gold, silver, copper, nickel, and other metals. In order to obtain a reproduction—as, e.g., a medal or similar object—a mold or cast is made on which the layer of metal is to be deposited by the current. This is sometimes of an inferior metal, as base or white metal; or, as in the case of type, of a mold made of some nonconducting material, such as wax or gutta-percha, which must be carefully brushed over before immersion with very finely powdered graphite. (See PRINTING.) In order that the metal to be deposited may adhere perfectly to the object to be plated, it is necessary that it shall be perfectly clean; it is therefore usually dipped in a cleansing solution, as of an acid or a caustic alkali, and then rinsed in water to remove all traces of the cleansing solution. The Bunsen, Daniell, Grove, and Smee batteries are often used to supply the current for electroplating small objects; but for commercial purposes it is customary to employ a dynamo machine. The solutions employed in electroplating are very numerous; but in ordinary commercial practice they consist of the following salts dissolved in distilled water: for *gold*, a solution of gold cyanide and potassium cyanide; for *silver*, a solution of silver cyanide and potassium cya-

nide; for *copper*, an ammoniacal solution of copper and potassium cyanide; for *nickel*, a solution of nickel and ammonium sulphate, or of the corresponding chloride. The electrolysis is effected in a convenient bath, which, when small objects are to be plated, may be of glass or porcelain, but in commercial practice is a trough lined with a nonconducting material. The latter may be wood or cement, in the case of silver; zinc, in the case of copper; and asphaltum, in the case of nickel. The object on which the metal is to be deposited is connected by a wire with the negative electrode of the battery, while the positive pole is connected with an anode of the same metal which is to be deposited on the object, thus closing the circuit. As fast as the solution is decomposed the liberated acid dissolves the metallic anode, in consequence of which the solution is kept in about the same state of concentration.

See ELECTROCHEMISTRY, INDUSTRIAL.

ELECTROSCOPE (from Gk. ἤλεκτρον, *ēlektron*, amber + σκοπεῖν, *skopein*, to look). An instrument for the detection of the presence of electricity. It depends for its action on the principle that bodies charged with like electricity repel, while those charged with unlike electricity attract, each other. The ordinary pith ball suspended on a silk thread is the simplest form of the instrument. The most common type of electroscope is that devised by Bennet in 1787 and

ELECTROSCOPE.

known as the gold-leaf electroscope. It consists of two strips of gold leaf, or thin aluminium foil, suspended from the lower extremity of a conductor within a glass bottle or jar. The upper end of the conductor terminates in a ball,

or a plate in case the instrument is to be used as a condensing electroscope. (See CONDENSER.) If a body charged with positive electricity is brought near to the knob of the electroscope, the negative electricity will be attracted to the knob and the positive repelled to the leaves, which then diverge. If now the finger is touched to the knob, the positive electricity is drawn off and the leaves collapse, while the negative electricity is held bound. Removing the charged body, the leaves will then diverge again, charged with negative electricity. In this case the instrument can be used to determine the nature of the charge of a body brought near it, as with a positive charge the leaves will collapse, and with a negative charge spread farther apart. In the Bohnenberger electroscope a strip of gold leaf is suspended between the poles of a dry pile (q.v.). If a charge is communicated to the gold leaf, it will be deflected towards one or the other of the two poles.

Much use has been made of the gold-leaf electroscope in the study of radioactivity, and several forms of the instrument have been devised that are used as electrometers rather than electroscopes. For the sort of measurements necessary in the study of the natural ionization or conductivity of the atmosphere, and the like, a well-designed gold-leaf electrometer has as great sensitiveness as a quadrant electrometer, is almost as reliable, and has the advantage of extreme simplicity. For a description of these modern electroscopes, consult Rutherford, *Radioactivity* (Cambridge, 1905). See TERRESTRIAL ELECTRICITY.

ELECTROSTATICS. See ELECTRICITY.

ELECTROTAXIS (Neo-Lat., from Gk. ἤλεκτρον, *ēlektron*, amber + τάξις, *taxis*, arrangement, from τάσσειν, *tassein*, to arrange). The sensitiveness of motile organisms to the direction of an electric current passing through the medium in which they are living. In given strengths of current some organisms orient themselves parallel to the lines of the current and swim towards the anode (positive), others towards the cathode (negative), and still others orient themselves and swim at right angles to the line of the current (*dia*). Variation in the strength of the current causes a reversal of response in some cases. It bears the same relation to electrotropism that chemotaxis does to chemotropism. See ELECTROTROPISM.

ELECTROTROPISM (from Gk. ἤλεκτρον, *ēlektron*, amber + τροπή, *tropē*, a turning, from τρέπειν, *trepein*, to turn). Sensitiveness of plant organs to the electric current or to electrical radiations; so called in analogy to other tropisms. (See GEOTROPISM, etc.) The response of plant organs to electrical radiations has been little studied, and the data justify no conclusions. To a current of low strength plant organs show a negative response (cathodic), to strong currents positive bending (anodic); and to currents of intermediate strength no reaction. It is the strength of the current passing through the organ itself rather than the bathing liquid that determines the bending. While the negative curvature is a true tropic response, the positive is not, but is due to the injury and cessation of growth of the organ on the anodic flank. An organ showing positive bending soon completely succumbs. In the case of negative bending in roots the tip is the perceptive zone and the quantity of stimulus law apparently applies. The injury in positive bending is probably due to the accumulation of poisonous ma-

terials (anodes) in the cells of the anodic flank.

ELECTROTYPING. See ELECTROCHEMISTRY, INDUSTRIAL; ELECTROPLATING; PHOTO-ENGRAVING; PRINTING.

ELECTRUM (Lat., Gk. *ἤλεκτρον*, *ēlektron*, amber, probably on account of its color, *ἤλεκτρος*, *ēlektros*, alloy of gold and silver). A term applied to native alloys of gold and silver. According to Pliny, the term "electrum" was applied to native gold containing at least 20 per cent of silver. Electrum was used since the seventh, and possibly even since late in the eighth century B.C. Its earliest usage was limited to purposes of inlaying, but later it was very extensively used as a material for coins.

ELEGIT (Lat., he has chosen), WRIT OF. A form of execution first authorized by the Statute of Westminster (13 Edw. I, c. 18), for the seizure and sale of one-half the lands owned by a judgment debtor. At common law land was not liable for the debts of its owner, because its forced sale to a stranger would have resulted in the destruction of the feudal relation of lord and tenant. By the Statute of Westminster, however, the judgment creditor was allowed to choose between a writ against the debtor's land and an execution by writ of fieri facias against his person or chattels. The new writ was called an *elegit*, because it represented this choice or election on the part of the creditor. The creditor, upon the writ, was regarded as having a half estate in the lands so held, not unlike the modern mortgage, which estate, because it was held as security for a personal debt, was treated as personal property ("chattel real" was the technical description) which would descend to the creditor's executor and not to his heir. The payment of the debt for which the writ was levied divested the estate by *elegit* and revived the title of the debtor. This remedy by *elegit* proved so convenient that it was subsequently extended (1 and 2 Vict., c. 110, § 11) so as to permit the seizure of the whole of the debtor's lands, and in this form it has survived to the present time in England and some of the United States. In most of the States, however, it has been superseded by other and simpler devices for securing the satisfaction of a judgment. Originally the creditor could only hold the lands—taking the rents and profits until the debt was satisfied; but the power to sell and apply the proceeds to the debt is now usually an incident of the estate by *elegit*. See EXECUTION, and consult the authorities there referred to; also Blackstone's *Commentaries on the Laws of England* (4th ed., 2 vols., Chicago, 1899) and Kent's *Commentaries on American Laws* (14th ed., 4 vols., Boston, 1902).

ELEGY (Lat. *elegia*, Gk. *ἐλεγία*, *elegeia*, elegy, from *ἔλεος*, *eleos*, mourning song). A word employed at an early period by the Greeks to designate a poem, usually short, written in distichs. (See DISTICH.) The alternation, peculiar to this measure, of the hexameter with the pentameter gives to this species of poetry its individual character. Of the numerous elegies of the Greeks, few have come down to us. Those still extant consist partly of encouragements to patriotism. Among the Romans, the term "elegy" was applied especially to love poems. Catullus was the first good Roman elegiac writer; after him came Propertius, Tibullus, and Ovid. Tibullus, in particu-

lar, brought the erotic elegy to its highest perfection. (Consult Jebb, *The Growth and Influence of Classical Greek Poetry*, pp. 95-103, Boston, 1894, and the introduction to K. F. Smith's edition of Tibullus, New York, 1913.) In modern times the term elegy is applied where a tone of melancholy pervades a poem. In English the word is generally understood as a name for lyrics that are laments over the dead, as, e.g., Milton's *Lycidas*, Shelley's *Adonais*, and Arnold's *Thyrsis*. The dirge is a kind of elegy, but, specifically, a funeral lamentation, expressive of a more immediate and poignant grief than the reflective sadness of the elegy.

Elegy, in music, is a composition depicting feelings of mourning, sadness, longing or ardent desire, and love.

ELEGY WRITTEN IN A COUNTRY CHURCHYARD. A poem by Thomas Gray (q.v.). It was finished in 1750, although it was begun seven or eight years before. The original churchyard is thought to have been that of Stoke Poges in Buckinghamshire. The poem first appeared on Feb. 16, 1751, rapidly ran through a number of editions, still retains its popularity, and has become an English classic.

ELEK'TRA. A music drama by Richard Strauss (q.v.), first produced at Dresden, Jan. 25, 1909; in the United States, Feb. 1, 1910 (New York).

ELEMENTAL SPIRITS. Beings who, according to the popular belief of the Middle Ages, presided over the four "elements," living in and ruling them. In a work attributed to Paracelsus the elemental spirits of fire are called salamanders; those of water, undines; those of the air, sylphs; and those of the earth, gnomes.

ELEMENTARY SCHOOLS. See COMMON SCHOOLS; SCHOOLS.

ELEMENTS. In astronomy, the numerical quantities employed in computing the position of a planet at any time. They are (1) the semimajor axis of the orbit; (2) the eccentricity; (3) the inclination of the plane of the orbit to the plane of the ecliptic; (4) the longitude of the ascending node; (5) the longitude of perihelion; and (6) the epoch. Sometimes the period, or the mean angular daily motion, which, by Kepler's Third Law, depends on the semi-major axis of the orbit, is also given. See COMET; PLANETS; ORBIT.

ELEMENTS, CHEMICAL. See CHEMISTRY; ATOMIC WEIGHTS; PERIODIC LAW.

ELEMENTS, CONSCIOUS. One of the principal problems of psychology is to analyze into their simplest constituent processes the mental complexes (perceptions, ideas, emotions, actions) that occur in everyday experience. These simplest, unanalyzable processes are termed the "elements of consciousness." See CONSCIOUSNESS.

We must, first of all, get a clear understanding of the elements of mind. 1. There is practically universal agreement among experimental psychologists that the structural elements of mind are two—sensation and affection (see these terms). All intellectual experiences reduce to sensation; all emotional and volitional experiences are compounds of sensation and affection. The mental organism is, so to speak, made up of these two types of process, as the bodily organism is made up, from the anatomical standpoint, of certain forms of cells. Both elements are determined by analysis and abstraction; neither

occurs alone in conscious experience. In the case of affection the final court of appeal is introspection; that is simple which self-observation declares to be simple. In the case of sensation there are two possibilities of decision. We may regard sensation (a) as a psychological ultimate or (b) as a psychophysical ultimate. (See PSYCHOPHYSICS.) Thus, the color red is unanalyzable in introspection; it is a psychological sensation. But in psychophysics red is the resultant of a chromatic (red) and an achromatic (white or gray) excitatory process. Psychophysically, therefore, the color is a fusion quality—a perception, not a sensation. It is immaterial which of the two “ultimates” we take as the basis of our reconstruction of mind from the elements, but we must be careful not to confuse them. 2. Psychologists, again, are fairly well agreed upon the question of the principal mental functions, though they differ as to which of these should be considered elemental. Brentano posits three ultimate functions—presentation or ideation, judgment or belief, and interest or emotion (love and hate). Stout recognizes cognition (including, as integral constituents, sentience, simple apprehension, and belief) and volition; this latter includes the fundamentally distinct functions of feeling (being pleased and displeased) and conation (desire and aversion). Wundt, on the other hand, regards impulse, a volitional process compounded structurally of sensation and affection, as the one typical form of mental function from which all the rest are derivative. 3. Impulse is further, for Wundt, the primordial manifestation of mind. This view is, of course, not shared by those who regard the reflex movement as primitive and believe that mind has in some way been superinduced upon unconscious bodily activity. In any case, the genetic definition of “element” must be sharply distinguished from the structural definition. See ACTION.

ELEMENTS, ELECTROCHEMICAL, ORDER OF. See ELECTROCHEMISTRY, GENERAL; CHEMISTRY.

ELEMENTS, SACRAMENTAL. See LORP'S SUPPER.

ELEMI, él'-mī (Fr. *élémi*, of doubtful etymology). A fragrant resinous substance, obtained from different plants of the family Burseraceæ. It was formerly brought chiefly from Egypt or Ethiopia and was referred to a tree called *Amyris plumieri*. Part of the elemi of commerce is now obtained in America, from trees of other genera of the same family, particularly *Protium icicariba*. In dry weather incisions are made in the bark, from which the resinous juice flows abundantly, hardens in the sun, and becomes brittle with age. Mexican or Vera Cruz elemi is derived from several species of *Bursera*. Manila elemi is produced by *Canarium commune*. Elemi is seen in the trade usually in large, pale yellow, semitransparent masses; fragile, softening by the heat of the hand; with a smell somewhat resembling that of fennel. It is soluble in alcohol and leaves a white crystallizable residue, which is very light, inodorous, and tasteless, and which is called elemine. The properties of elemi, however, chiefly depend on a volatile oil, which may be obtained from it by distillation. Elemi is

used in the preparation of stimulant plasters and ointments and is extensively used as an incense in Eastern countries.

ELE'OLITE. See ELÆOLITE.

EL'EPHANT (AS. *elpend*, OF. *olifant*, *elifant*, Lat. *elephus*, from Gk. *ἐλέφας*, possibly from *ἐλ-*, *el*, horn + *-epas*, *-ephas*, Lat. *ebur*, ivory, from Egypt. *abu*, *ab*, Copt. *edou*, *ehu*, elephant). An ungulate mammal of the suborder

FIG. 1. SKULL OF AN INDIAN ELEPHANT.

Vertical section of the skull, with the molars and incisor (tusk) of one side: a, brain cavity; b, cavernous upper part of the cranium, showing its cellular cavities; c, condyle; d, d, molars; e, tusk.

Proboscidea and family Elephantidæ, representing by two species the largest existing land animals. The ordinary height at the shoulder is about 8 feet, but occasionally exceeds 10 feet, and has been known in one case, in Ceylon, to reach 12 feet. The weight of a large elephant is about five tons, the body being very bulky in proportion to its height. To sustain this weight, it is furnished with limbs of colossal thickness and strength, which are also remarkably straight, each bone resting vertically on that beneath it. In lying down, the elephant does not bring his hind legs under him, like other quadrupeds, but extends them backward as a man does when kneeling. The elephant's pace, when exceeding a walk, is neither a trot nor a gallop, but a sort of shuffle, the speed of which is increased or diminished without change of gait.

Structure. The head in elephants is large; the neck is short and thick, the long flexible proboscis enabling the animal readily to reach objects on the ground or at a height or distance of several feet. A great extent of bony surface in the head affords attachment for muscles destined to move and give power to the proboscis or trunk, yet the head is light in proportion to its bulk, as a great space separates the internal and external tables of all the bones of the skull, except the occipital bones, so that the brain chamber is but a small part of the whole head. The space between the tables of the bones is occupied by cells, some of which are 4 or 5 inches in length, which connect with each other and are filled with air, making the vast skull comparatively light.

Trunk. The nasal bones of the elephant are scarcely more than rudimentary; but the tapering proboscis, to the very extremity of which

the nostrils are prolonged, is nearly 8 feet in length. Besides the great muscles connected with it at its base, it is composed of small muscles variously interlaced, which Cuvier estimated at not much less than 40,000. The trunk can be coiled around a tree and employed to tear it from its roots; it is a formidable weapon of offense and defense and is far more employed in this way than the tusks. Its extremity may be wound around a small handful of grass or a slender branch, and it is capable of picking a surprisingly small object from the ground. To fit it for such actions as a man might perform by a hand, the trunk of the Indian elephant is furnished at the extremity with what may be likened to a finger and thumb—on the upper side, an elongated process, soft, strong, flexible, and endowed with the most delicate sense of touch; on the under side, a kind of tubercle against which this process may be pressed. All the food of the elephant is gathered and conveyed to the mouth by the trunk; by means of the trunk, also, it drinks, sucking up a quantity of water sufficient to fill it and then discharging the contents into the mouth. Valves at the base of the trunk prevent the water from going too far up the nostrils. The trunk is constantly employed by elephants in providing in many ways for their comfort and enjoyment, as in throwing dust or spouting water over their backs, two practices to which they are greatly addicted. Their friendly caresses are also given by the trunk, and through it they make a loud shrill sound, indicative of rage. With the trunk, also, they are able to strike powerful blows.

The sense of smell is very acute in the elephant, as is also that of hearing. The ears are large and pendulous; the eyes are small.

Teeth. Elephants have no canine teeth, nor have they any incisors in the lower jaw. The upper jaw is furnished with two incisors which, in perfection, become enormous tusks, sometimes weighing from 150 to 200 pounds. They are preceded by milk teeth, shed at an early age, and they consist almost wholly of solid dentine, the fine elastic quality of which renders it invaluable as ivory (q.v.) for various uses in the arts. A peculiarity of its structure is that in a cross section "striæ proceed in the arc of a circle from the centre to the circumference in opposite directions, . . . as in the engine turning of a watch." The tusks vary greatly in size, being sometimes very small, and they are often malformed or wholly broken off. Elephants employ them for such uses as grubbing up edible roots or loosening the roots of trees which they cannot otherwise tear from the ground; as weapons (by thrusting), especially in maintaining discipline

FIG. 2. MOLAR TEETH.

a, penultimate molar; b, germ of the last molar; c, bony capsule of the alveolus, which moves forward with the tooth.

in a herd; and in domestication for carrying light sticks of timber, held in place by the trunk. The molar teeth of the elephant are developed in succession; and, at least in the Indian elephant, never more than two are to be seen in the same side of a jaw at one time. The

first molars cut the gum in about two weeks after birth and are shed about the end of the second year. The sixth molars, which are also believed

FIG. 3. MOLAR OF INDIAN ELEPHANT.

d, dentine; d', dentine worn down to common base; e enamel; c, cement.

to be the last, are supposed to appear about the fiftieth year of the elephant's life. The molar teeth of the elephant are remarkable for their great size and for the extreme complexity of their structure. They are composed of vertical plates of bony substance, separately enveloped in enamel and soldered together by a third substance, "cement," more resembling bone than enamel. Each succeeding tooth is not only more complex, but occupies a greater space in the jaw than its predecessor. Although formed from a single pulp, the molar tooth of an elephant resembles an aggregation of teeth; and in the earlier stages of its growth, when the cement is not yet deposited, it seems as if many separate teeth were soldered together. As the surface of the tooth is worn down by mastication, the harder enamel is exposed in elevated ridges; from the peculiar manner of its growth, the anterior part begins to be employed and to

FIG. 4. MOLAR OF AFRICAN ELEPHANT.

Grinding surface of the penultimate lower molar. Letters as in Fig. 3.

be worn away while the latter part is still in process of formation.

Functions. The digestive apparatus of the elephant is similar to that of other herbivorous animals; but the stomach, which is of a very lengthened and narrow form, has near the gullet a reservoir for water, capable of containing several gallons, while a peculiar muscle, connecting the windpipe and gullet, enables the animal to regurgitate the fluid, which may then be sucked from the mouth into the trunk and squirted over the body or at some offending man or animal.

The female elephant has only two teats, situated between the forelegs. The young suck with the mouth and not with the trunk. They are suckled for about two years. The period of gestation is also nearly two years, and a single young one is produced at a birth.

The skin of the elephant is very thick, of a dark-brown color, and in the existing species has scarcely any covering of hair. The tail does not reach to the ground and has a tuft of coarse bristles at the end. The feet have toes, each incased in a kind of hoof.

Habits, etc. Elephants live in herds, not

ELEPHANTS

1. INDIAN ELEPHANT (*Elephas indicus*), with howdah

2. AFRICAN ELEPHANT (*Elephas africanus*)

generally numerous, but several herds often congregate together in the same forest or at the same place of drinking. Each herd has a leader, generally the largest and most powerful animal. The leader seems to exercise much control over the herd, gives the alarm in case of danger, and seems to examine and decide for the whole herd as to the safety of proceeding in any particular direction. A family resemblance is usually visible among the elephants of the same herd; some herds are distinguished by greater stature, and others by more bulky form and stronger limbs; some by particularly large tusks, some by slight peculiarities of the trunk, etc. In the East Indies distinctions of this kind have long been carefully noticed, and some are considered as "high-caste," others as "low-caste," elephants. An elephant which by any cause has been separated from its herd seems never to be admitted into another, and these solitary males are particularly troublesome in their depredations, exhibiting an audacity which the herds never show; they are also savage and much dreaded, while from a herd of elephants danger is rarely apprehended. These remarks apply especially to the Asiatic species.

The favorite haunts of the African elephant are mountainous districts with a scattered tree growth; but the Asiatic species keeps itself in the depths of forests, particularly in mountainous regions, where they browse on branches or eat herbage, roots, etc., and from which they issue chiefly in the cool of the night to pasture in the more open grounds. They feed largely on the young shoots of palm trees, and crush and eat the coconuts, after rolling each one under foot to rub off the husk; and they often do vast damage to crops.

Elephants delight in abundance of water and enter it very freely, often remaining in it for a considerable time and with great evident enjoyment, swimming with ease and skill.

Two species of elephant only survive the decay of a family much more numerous and widespread in the geological period that preceded the present—one African and the other Asiatic. For fossil and extinct species, see section *Fossil Elephants*, and see also MAMMOTH; MASTODON.

African Elephant. This species (*Elephas*, or *Loxodonta, africanus*) is confined to Africa, and until the settlement of South and East Africa during the last half of the nineteenth century it ranged over every part of the continent south of the Sahara and Nile deserts in surprising abundance. It disappeared south of the Zambezi and from near the coast as the century closed, but throughout the equatorial regions it is still numerous and is likely to remain in fair numbers, as European governments have agreed upon various laws, including a close season for females, and an export duty on the tusks, by which it is hoped to prevent rapid extermination. This species is frequently 10 feet in height, the males surpassing the average height of the Asiatic species, but the females are smaller. Both sexes have tusks—a fact which contributes to the diminution of the species, as the females are as liable as the males to be killed for the sake of their ivory. The crowns of the molar teeth exhibit a lozenge pattern of grinding surfaces, and the teeth differ in structure from those of the Indian elephant. There are but three toes on the hind feet in the East African forms, but four in those living in West Africa. The African ele-

phant has been separated into 12 or 15 subspecies, based on more or less definite characters, of which four may prove to be valid species. Some are dwarfed in size, hardly taller than a man.

This elephant was familiar to the ancient Egyptians and is believed to have been used by them in war at an early period. Those which Hannibal took with him upon his famous expedition against Rome are presumed, rather than known, to have been of this kind, but possibly were Asiatic. At any rate, African elephants were never, or very rarely, seen in Europe from the show days of Imperial Rome until about 1860, since which perhaps 100 have been taken there alive, nearly all of which soon died of disease. There seems to be no reason why the African elephant may not be tamed and educated as well as the Asiatic species. That the African savages, who frequently might capture calves, do not rear them is to be explained not only by the animal's uselessness to them, but by the impossibility, in the case of most tribes, of keeping the calf alive until it is able to quit a milk diet and live upon grass and leaves. This elephant, then, is of service to mankind only as the source of nearly all the living ivory that comes to the market.

Asiatic Elephant. The more familiar Indian elephant (*Elephas indicus*, or *maximus*) is prominently distinguished from the African by having a rather high, oblong head, with a concave forehead, ears hardly more than half as large, and the eyes smaller. Tusks are present only in the males and are only about half as large or heavy as African tusks; and the molar teeth are different. There are four toes on the hind feet, and the trunk terminates in the flexible finger-like prolongation already described. The height of the average male is about 9 feet and of the average female about 8 feet; but specimens exceeding 10 feet in height are not very rare. The weight is from 2 to 3 tons. They become fully grown at the age of 25, but their teeth do not show complete maturity until some years later. Several captive specimens have been known to live a century, and it seems likely that in a wild state they may sometimes reach an age of 150 years. Their distribution is somewhat less extensive than formerly, but the species ranges at the present day through the forested regions from Ceylon, the western Ghats, and Himalayan foothills eastward to Cochin-China and southward to Sumatra. They keep to the shady forests, rarely showing themselves in the open except at night or on cloudy or rainy days, for they soon feel great distress from exposure to the sun.

Elephants breed not rarely in a state of domestication, although where owned for breeding purposes, as in Siam, the studs are kept up by the capture and addition of new individuals. They are generally tamed within a few months after they are captured; some degree of severity being employed at first, which, however, as soon as the animal has begun to respect the power of man, is exchanged for kindness and gentleness of treatment. Elephants intended for domestication are captured in various ways. It was formerly common to take them in pitfalls, but in this way they were often much injured. Another method frequently practiced is by the aid of tame elephants. Male elephants chiefly are captured in this way, the decoy elephants em-

ployed being females, trained for the purpose. With these the hunters very cautiously approach the animal they mean to capture. Two of the females take their places, one on each side of him, while the men contrive to get beneath their bodies and to pass ropes round the legs of the intended captive. His two hind legs are fastened together by six or eight ropes, another rope keeping them tight at the intersections, and a strong cable with a running noose is attached to each hind leg. About 20 minutes are usually spent in fixing the necessary ropes, profound silence being maintained if the process goes on unobserved, or some of the other hunters distracting the attention of the elephant from those who are engaged in this work; and when at last, becoming sensible of his danger, he tries to retreat, an opportunity is soon found of tying him, by means of the long cables which trail behind him, to some tree strong enough for the purpose. His fury then becomes ungovernable, and it is not until he has thoroughly exhausted himself and begins to suffer severely from fatigue, thirst, and hunger, that the next steps are taken towards taming him.

But these huge animals are not always captured singly; whole herds are often taken at once. This is accomplished by means of an inclosure, towards which the elephants are driven by great numbers of men encircling a considerable space and contracting the circle by slow degrees. Weeks, or even months, are spent in this operation, and at last the elephants, hemmed in on every side except the mouth of the inclosure, enter it, and the gate is immediately closed. The modes of contracting the inclosure are different in different parts of the East. Tame elephants are sometimes sent into it, and the captives are in succession made fast to trees there, in a way somewhat similar to that practiced in capturing single elephants.

These elephants first became known in Europe from their employment in the wars of the East. They have been taught to cut and thrust with a kind of scimitar carried in the trunk, and it was formerly usual for them to be sent into battle covered with armor and bearing towers on their backs which contained warriors. But the principal use of the elephant in war is for carrying baggage and for dragging guns. Elephants are used in the East for carrying persons on their backs, a number being seated together in a howdah, while the driver (mahout) sits on the elephant's neck, directing it by his voice and by a small goad. Elephants have always a conspicuous place in the great processions and state displays of Eastern princes, and white elephants—albinos—are peculiarly valued. Elephants are also employed in many kinds of labor and display great sagacity in comprehending the nature of their task and adapting themselves to it.

Fossil Elephants. The ancestry of the elephants, or Proboscidea, can be traced back through a continuous line to a small primitive elephant living in Oligocene times in Egypt called *Palæomastodon*. This form had an elongated lower jaw, with well-developed, forward-directed incisors, small premolars and molars, with three pairs of tubercles. All the bones of *Palæomastodon* except the skull and the teeth were almost generically similar to those of the modern elephant. A cleft of still earlier proboscidean evolution is found in *Mærittherium*. This animal was about the size of a tapir, and lived in Upper

Eocene and Lower Oligocene times. Although there is no doubt of relationship, yet the differences in body, skull, and dentition between this form and its successor *Palæomastodon* are great, and *Mærittherium* is proboscidean in only a very general way. In fact, it was probably semi-aquatic and lived in streams and marshes, and while unquestionably near the ancestral stem of the elephants, it was also very likely the ancestor of the modern *Sirenia*, the wholly marine manatee and dugong. They are the least specialized of the modern ungulates, for during their known history they have progressed only in respect of the development of the trunk or proboscis, the substitution of tusks for the incisor teeth, and the acquirement of an abnormal molar dentition. In the early Miocene time they are found with their proboscidean characters well developed, and the chief genera, *Gomphotherium*, *Mastodon*, and *Elephas*, which succeed each other in geologic time, present a progressive evolutionary series. In the earlier forms the bony structure of the facial region of the skull is less thickened than it is in later forms, indicating a lesser muscular attachment for a smaller proboscis. The tusks augment in size in the successive genera, and the teeth increase in complexity as to their crowns. The molar teeth of *Gomphotherium* have only 2 or 3 transverse ridges, *Mastodon* has 2 to 5, *Stegodon* has 13, and *Elephas* has 27. This complexity is due to folding of the enamel into transverse ridges, the number of folds advancing in the successive genera. The size of the molars also increases, and in the latest genus, *Elephas*, they have become so large that only two or three can be in position in the jaw at one time. The brunt of the chewing falls upon the anterior molar, and as this is worn out it is pushed forward out of the front of the jaw, and the space behind is filled by a new molar that rises from a socket at the back of the jaw. Fossil Proboscidea appear in the Miocene and Pliocene of North America and Europe and in the Pliocene of South America, but at the end of the Pleistocene they disappeared from those countries, having emigrated to Asia and Africa, where their descendants are now living. ELEPHANT, ORDER OF THE. A Danish Order of uncertain origin. It dates back, according to some authorities, to Canute VI in the twelfth century, and according to others to Christian I in the second half of the fifteenth. The decoration is highly valued, because rarely conferred. The badge is a white enameled elephant, caparisoned in blue, with a red tower on its back and a negro driver. The collar consists of alternate towers and elephants. The ribbon is blue.

EL'EPHAN'TA (locally, *Gharapuri*). An island 4 miles in circuit, in the harbor of Bombay, East India, about 6 miles to the east of that city. It took its European name from the huge figure of an elephant, cut out of a detached rock, near its principal landing place, which, however, gradually crumbled away and was removed. It is supposed that a city flourished on the island between the third and tenth centuries. From that era date four Brahmanic temples dug out of the mountain, the roofs supported by curiously wrought pillars of various forms and magnitudes, and the walls thickly sculptured into all the forms of Hindu mythology. The largest of the excavations, or Great Cave, is nearly square, measuring 133 by 130 feet, its roof supported by six rows of six columns each. Immediately fronting its main entrance stands a bust of a three-headed deity, with a height of 18 feet and a breadth of 23, representing Siva, the trinity of creation, preservation, and destruction. The great temple is used by the Bania caste for the Sawa festivals. Pop., 1901, 480. Consult Burgess, *The Rock Temples of Elephanta* (Bombay, 1871), and Ferguson and Burgess, *The Cave Temples of India* (London, 1880).

THE ELEPHANT BEETLE.

ELEPHANT BEETLE. A gigantic lamellicorn beetle (*Megasoma elephas*) of Central

America. Its total length is about 5 inches, two-fifths of which belongs to a strong, upturned forked horn projecting from the head. The ground color of the whole insect is black; but, with the exception of the front horn, the entire surface is thickly covered with dense, soft, upright, yellowish fur. As this fur is easily rubbed off, most specimens are partly bare. Another species, *Megasoma acteon*, of Nicaragua, is as large or larger, and its fur varies from chestnut on the horn to yellow on the elytra.

ELEPHANT FISH, or SHARK. A name for the chimæra (q.v.).

EL'EPHANTIASIS (Lat., from Gk. ἐλεφαντίασις, from ἐλέphas, *elephas*, elephant, so called because the skin becomes wrinkled like the hide of an elephant). A medical term formerly applied to any marked hypertrophy of the skin and areolar tissues, but now generally used to designate a disease accompanied by œdema and progressive hypertrophy of the cutaneous and areolar tissues. There are two diseases called by the name. One is the elephantiasis of the Greeks, which is regarded as the same as the Eastern leprosy and as the *spedalskhed* of Norway, and the chief features of which are described in the article **LEPROSY**. In this affection the size of the limbs and the state of the epidermis are comparatively slightly altered. The other is the elephantiasis of the Arabs, identical with the *Barbados leg* (q.v.) of the East and West Indies and the Levant, where it is endemic. The disease may come on slowly, without constitutional symptoms, but the acute form is attended with headache, fever, nausea, and vomiting; the leg or arm or scrotum then becomes inflamed, swollen, and tender; bullæ may form and burst, exuding serum. In a few hours or a few days the attack ends. But others follow, and the affected part becomes larger and larger, each attack leaving it greater in size. The scalp, face, or female genitals may become enlarged, as well as any other part of the body; but the leg is the most often affected. Manson, in 1883, established the fact that endemic elephantiasis is due to the presence in the lymphatics of a parasitic worm called *Filaria sanguinis hominis*. (See **FILARIA**.) The disease may be congenital. Turner, of Samoan experience, believes some cases are due to malarial infection. A condition of lymphostasis may be produced by any inflammation of the skin and subcutaneous tissues, or by removal of the lymph nodes in the groin or axilla. Thus lupus, syphilis, varicose ulcers, or other causes of recurring lymphangitis, are factors in favorable surroundings. Rest in bed, with elevation of the affected part, elastic bandaging, massage, galvanism, palliate some cases; change of climate and quinine cure a few; amputation may be necessary in some instances.

EL'EPHANTINE (Lat., from Gk. Ἐλεφαντίνη). The Greek name of an island in the Nile, just below the First Cataract and opposite Assuan (q.v.), the ancient Syene. From very ancient times the island was a trading post whither the Nubians brought ivory and other wares for barter with the Egyptians; from this circumstance it derives its Egyptian name, 'Abu, 'Ivory town,' of which the Greek name is a translation. It is called by the Arabs *Jazīrat Aswān*, 'the island of Assuan,' or simply *El-Jazīreh*, 'the island.' The whole southern end of the island is covered with rubbish heaps which have accumulated over the ruins of the ancient city.

Near by are the foundations of a small temple built by the Emperor Trajan, and a granite gateway on which are sculptures representing Alexander, son of Alexander the Great, making offerings to the gods of Elephantine and especially to the ram-headed god Knum. Farther north stood a temple built by Amenophis III and another built by Thothmes III. Both existed in a fine state of preservation until 1822, when they were demolished for the sake of the building material they contained. The most interesting relic remaining upon the island is the Nilometer (q.v.), of which a description is given by Strabo. It was restored and placed in use in 1870 by the Khedive Ismail Pasha. Consult: Champollion, *Notices descriptives* (Paris, 1844); Mariette, *Monuments of Upper Egypt* (London, 1887); Edwards, *A Thousand Miles up the Nile* (ib., 1888); Meyer, *Der Papyrusfund von Elephantine* (Leipzig, 1912).

ELEPHANTINE PAPYRI, THE. A collection of complete documents, and fragments of such, written on papyrus, found on the island of Elephantine near the First Cataract of the Nile or originally coming from that place. One of them was secured by the Imperial Library at Strasburg in 1898 and published by Euting in 1903. In 1904 Robert Mond purchased at Assuan a number of others which had come over from the island. These were published by Cowley and Sayce in 1906. Through the German excavations of the ancient city at the southern end of the island, in 1906-08, others were brought to light which were published by Sachau in 1907 and 1911 and by Rubensohn in 1907. Those written in Aramaic come chiefly from the archive of the Jewish military colony. Some of them are dated—the earliest apparently in 494 B.C., the latest in 404 B.C. The most important are copies of letters sent to Bagoas, the Persian Governor of Palestine, Johanan, the high priest in Jerusalem, and the sons of Sanballat in Samaria, and refer to the Yaho temple in Yeb which was destroyed by the priests of Chnub in 411 B.C. One of them deals with the observance of the Passover. Others are records of the transfer of property, marriages, and the like. There are also copies in Aramaic of the Behistun inscription (see BEHISTUN) and of the story of Ahikar, as well as numerous documents in Greek from the Ptolemaic period. The significance of the Elephantine papyri lies in the fact that they reveal the existence of a Jewish colony at the southern end of Egypt, with its own Yaho temple and its peculiar cult. The temple existed as early as 525, since it is distinctly stated that it was spared by Cambyses when he destroyed all the temples of Egypt. The colony may have come over in the time of Psammetichus I (663-609), after the concentration of the cult in Jerusalem by Josiah in 620 B.C., and may have consisted of mercenaries and their families coming from Bethel as well as from Judæan towns, since some of the deities they worshiped along with Yaho appear to be identical with some of those worshiped by the people of Bethel and Samaria. (See 2 Kings xvii. The priesthood at Elephantine does not seem to have been acquainted with the law in its complete form. (See PENTATEUCH.) Women had the right to divorce their husbands. Polytheism prevailed, though Yaho was the chief god. Consult: Euting, in *Mémoires de l'Académie des inscriptions*, vol. xi, p. 2 (Paris, 1903); Sayce and Cowley,

Meyer, *Der Papyrusfund von Elephantine* (2d ed., Leipzig, 1912); N. Schmidt, in *Journal of Biblical Literature*, vol. xxxiii, p. 1 (Boston, 1914).

ELEPHANT MOUND. A noted effigy mound in Grant Co., Wis., which, however, seems to have been intended for the effigy of a bear instead of an elephant. Consult *Report of Geological Survey for Wisconsin* (1873-74).

ELEPHANT SEAL, or SEA ELEPHANT. The largest species (*Macrorhinus leoninus*) of the hair-seal family Phocidæ, an inhabitant of the seas of the Southern Hemisphere. It is considerably larger than an elephant, being sometimes more than 20 feet in length, with a circumference of about 12 feet at the thickest part, which is at the chest, immediately behind the fore flippers; the body tapers towards the tail. The females are only one-half or one-third the bulk of the males. The color is grayish or blackish brown. The whole body is covered with very short hair, distributed in patches, giving it a spotted appearance somewhat like watered silk. The head is larger in proportion than in many seals; the eyes are very large and prominent, with eyebrows of coarse hair; the whiskers are composed of very long and coarse, spirally twisted hairs; there are no external ears; the canine teeth form massive tusks. The nose of the males is very remarkable, being prolonged into a kind of proboscis about a foot in length, which, however, seems to serve no purpose whatever except to that of an elephant's trunk, but it hangs flaccid on the face. During the breeding season the males have furious combats, the victor winning for himself a whole herd of females. When the proboscis is dilated, the voice of the sea elephant, which usually is like the lowing of an ox, is completely changed and becomes a loud and extraordinary gurgling. See Colored Plate of SEALS.

Sea elephants were to be found, at the beginning of the nineteenth century, in immense herds on the coasts of Kerguelen's Land, Juan Fernandez, South Georgia, the States Islands, South Shetland, the Falkland Islands, and the southern extremity of South America; but their numbers have been greatly reduced, and they are practically extinct in the region about Cape Horn and other easily accessible haunts. They migrate southward at the beginning of summer and northward at the approach of winter, thus avoiding the extremes of heat and cold. A single individual sometimes yields 20 gallons of excellent oil, which burns slowly, with a clear flame and without smoke or disagreeable odor. For this oil these animals have been hunted until now they are much reduced in numbers. Cuttlefish and other cephalopods seem to be their principal food, but remains of marine plants have also been found in the stomach. The skin is not at all valued on account of its fur, but its thickness and strength make it very useful for harness making and similar purposes. The flesh is black, oily, and indigestible, the tongue alone (salted) being esteemed palatable.

The second species of this genus, the northern

elephant seal (*Macrorhinus angustirostris*), was formerly common on the Pacific coast from Magdalena Bay north to San Francisco, a distance of 1000 miles. It is now on the point of extinction, being confined to the small island of Guadaloupe, off Lower California, where a herd of about 150 animals represent all the survivors of this great marine mammal. Dr. Townsend has recently studied this herd and has given a summary of knowledge of the group. Among new facts discovered is the length of the trunk in the live animal, which in a male 13 feet long measures 9 or 10 inches. This trunk is not capable of inflation, but can be retracted into heavy folds on top of the head by muscular action. The breeding season begins about March 1, and the period of gestation is 12 months. The young when born are black, and the yearlings have a call or scream unlike the voice of any other seal. The food is unknown, but in captivity live fish is preferred. A number of specimens were successfully transported to New York and lived for many months in the Aquarium.

Early descriptions of the elephant seal, in the voyages of Cook, Peron, Anson, and others, were tinged with much romance. A good modern and critical account of the animals, as observed on Kerguelen and neighboring islands, will be found in Moseley, *Notes by a Naturalist on the Challenger* (London, 1879). For the history and characteristics of the Californian species, consult Scammon, in *Fishery Industries* (United States Fish Commission, W. . . . 1884), where further references will be found; Townsend, "The Northern Elephant Seal," in *Zoologica*, vol. i, No. 8 (New York, 1912); Murphy, *American Museum Journal*, vol. xiii (ib., 1913).

ELEPHANT'S EAR. The popular name of *Colocasia antiquorum esculenta*, or, as it is known to the trade, *Caladium esculentum*, a Hawaiian or Fijian plant, with very large, bright green leaves, used to give subtropical effect in bedding. The rootstock is planted in good, moist soil out of doors or started in a hotbed or greenhouse and transplanted. In autumn it is stored where dampness and frost cannot reach it. In the Pacific islands the rootstock is extensively used for food, the poi of Hawaii being made from it. The plant is called taro. See Plate of EDELWEISS.

ELEPHANT'S FOOT. See DIOSCORIACEÆ.

ELEPHANT SHREW. An African shrew of the genus *Macroscelides*, so called on account of its proboscis-like nose, especially *Macroscelides typicus* of Cape Colony, and a very similar species (*Macroscelides rozeti*) of the Mediterranean border, known in Algeria as "rat-à-trompe." See JUMPING SHREW.

ELEPHANT TORTOISE. The giant land tortoise of the Galapagos Islands. See TORTOISE; EXTINCT ANIMALS.

ELETZ, ve-lêts'. See YELETZ.

ELEUSINE, el'ya-sî'né (Neo-Lat., from Gk. Ἐλευσίς, *Eleusis*, a city of ancient Greece). A genus of grasses, most of which are annuals. Two of the species—*Eleusine corocana* and *Eleusine stricta*, generally called millets—are grown as grain crops in the warmer parts of Asia and in Africa. A sort of bread is made from the seed, but it has a rather bitter taste. A beer is also brewed from it. The grasses are of rapid growth and are very productive in both grain and forage. *Eleusine indica* is a well-known species in the United States, especially

in the South, where it is known as goose grass and is considered a pest. Infusions of the seeds and other parts have some reputation as domestic remedies for certain ailments. Popular names for this grass are goose grass and yard grass.

ELEUSINIAN MYSTERIES (trans. of Gk. Ἐλευσίνια μυστήρια, *Eleusinia mystéria*). The sacred rites with which the annual festival of Demeter was celebrated at Eleusis (q.v.). The early Eleusinian tradition of their origin is preserved in the Homeric Hymn to Demeter. According to this, the goddess, while wandering in search of Persephone, came to Eleusis in disguise and was hospitably received by King Celeus. (See CERES; PROSERPINA.) In return she directed the establishment of a temple and mystic rites in her honor and showed to Triptolemus (q.v.) and other princes the use of grain. Later these rites seem to have been largely influenced by the Orphic movement of the sixth century B.C. (see ORPHEUS), to which may be attributed the introduction of Iacchus into the triad of Demeter, Kore, and Triptolemus, who seem to have been the earlier divinities. For the nature and celebration of this worship, see MYSTERIES; for the sanctuary, see ELEUSIS.

ELEU'SIS (Lat., from Gk. Ἐλευσίς. A town in Attica, near the northern shore of the Gulf of Salamis, not far from the confines of Megaris. It was the chief seat of the worship of Demeter and the scene of the celebration of the Eleusinian mysteries. (See CERES; ELEUSINIAN MYSTERIES; MYSTERIES.) The town was very ancient and in early times a rival of Athens, against whose supremacy in Attica it long held out. It finally submitted on terms which left its two priestly families—the Eumolpidae and the Ceryces—in control of the sanctuary and its rites, though in later times the Athenian state controlled the revenues of the temple. The sacred buildings were destroyed by Alaric (q.v.) in 396 A.D. Until 1882 excavations on this site had been few and unremunerative; but in that year the Greek Government appropriated the site of the ancient Eleusis to the Greek Archaeological Society, which, as director, began a series of excavations which have laid bare the entire sacred precinct. The temple of the two goddesses—Demeter and Kore—has disappeared, and even its site is uncertain; but the two Propylæa erected in Roman times, the Sacred Well, where Demeter rested, lesser temples, a Bouleuterion, or Council Hall, and the great terrace on which stood the Telesterion, or Hall of Initiation, in which the mysteries were celebrated, can be plainly traced. Before the Persian War the great Hall of Initiation was a rather small building at the foot of the rocky hill which formed the ancient Acropolis. After the war this structure was enlarged by cutting back into the rock: in the time of Pericles it was still further enlarged by the erection alongside it of another hall of about the same size. (See ICTINUS.) Probably these two halls had a common upper story, for both contain many large columns which must have been needed to sustain a heavy weight. In the fourth century B.C. the architect Philon of Eleusis added a great portico (183 feet by 37½) to the common front of these halls, and in Roman times, probably under Hadrian, the two buildings were thrown into one great hall (178 feet by 170), with 42 interior columns (seven rows of six columns each), and a series of eight raised

steps around the sides. On the steps sat, it is supposed, the *Mystæ*, the initiate; below, in the centre, the ceremonies took place. Probably both lower and upper stories were used in the celebration of the mysteries. The modern name for the little Albanian village on this site is Levsina. Consult: Gardner, *New Chapters in Greek History* (London, 1892); Diehl, *Excursions in Greece* (ib., 1893); Philios, *Eleusis, ses mystères, ses ruines, et son musée* (Athens, 1896); Frazer, *Pausanias* (2d ed., London, 1913). The reports of the excavations are to be found in the *Πρακτικά* of the Greek Archaeological Society, and in the *Ἐφημερίς Ἀρχαιολογική*; they are summarized in the excellent guidebook of Philios, who directed the work for many years. For a plan of the excavations, consult Baedeker's *Handbook to Greece* (4th Eng. ed., Leipzig, 1909).

ELEUTHERA, ê-lû'thê-râ. One of the Bahamas (q.v.), British West Indies, lying to the east of Nassau, and next to New Providence the most populous island of the whole chain (Map: West Indies, C 1). Area, 164 square miles. It is more fertile than most of its neighbors, surpassing all of them in the growth of pine-apples, oranges, and onions. Pop., 1901, 8733; 1911, 9533. The chief town is Governor's Harbor, with a fort and a good harbor.

ELEUTHERA BARK. See CASCARILLA.

ELEUTHERIA. See GREEK FESTIVALS.

ELEUTHERUS. Pope from 174 to 189. He is said to have received a letter from Lucius, alleged King of Britain, asking that missionaries be sent to his country to teach the Christian religion. The letter, which is not genuine, is found in the *Liber Pontificalis* and in Bede, *Historia Ecclesiastica*, vol. iii, p. 25. Consult Harnack, *Geschichte der altchristliche Litteratur* (Leipzig, 1893).

ELEVATED RAILWAYS. See RAILWAYS, section *Elevated Railways*.

ELEVATION (Lat. *elevatio*, from *elevare*, to raise, from *e*, out + *levare*, to raise, from *levis*, light; connected with Lith. *lengvus*, Gk. *ἐλαχὺς*, *elachys*, Skt. *laghu*, *raghu*, light). In astronomy, the height above the horizon of an object on the celestial sphere, measured by the arc of a vertical circle passing through the object. Thus, the elevation of the equator is an arc of the meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the meridian arc intercepted between the horizon and the celestial pole. It is the complement of the elevation of the equator and is always equal to the latitude of the place. The elevation of a star or any other point is similarly its height above the horizon and is a maximum when the star is on the meridian. See ALTITUDE.

In architecture the elevation is the geometrical representation of the exterior, or section of a building, which gives an appearance as if it were viewed from such a distance that no convergence of lines would be seen. Technically speaking, the elevation of a building is its vertical right-line projection. The elevation is one of the three drawings which are essential in designing any architectural structure, the others being the plan (q.v.) and the section (q.v.).

ELEVATION AND SUBSIDENCE. Terms applied to vertical movements of the earth's crust. The great movements of the earth's crust are ascribed to cumulative stresses in-

duced probably by the shifting of rock material at the surface through the agencies of weathering and erosion. While local areas may be elevated—i.e., carried farther from the centre of the earth—through the efforts of rocks to relieve themselves from great lateral stresses by bulging out, it is held by most geologists that large areas are seldom actually elevated, but that uplift is only apparent because of the subsidence of adjacent areas. In other words, it is believed that all parts of the crust are subsiding, some, however, faster than others, thus giving the impression that the adjacent areas are rising. If the sea bottom should subside, the water would flow away from the continental shores, and the continents would apparently rise, although in reality they might remain stationary. The great movements of uplift and subsidence are ordinarily considered in two great classes: (1) epeirogenic movements, or vertical movements of large areas such as continents, or large parts of continents; (2) orogenic, or mountain-making, movements—i.e., the movements which result in the folding and corrugation of the earth's crust into mountainous areas. See MOUNTAIN.

ELEVATOR. The modern high-speed passenger elevator is usually operated by electric or hydraulic power, and consists (1) of a rectangular car which moves up and down between guides in a shaft, or well, with doors opening into each floor, and (2) of the mechanism necessary to give this car its up and down movement, together with various devices to insure its safety and control. The passenger elevator has made possible the skyscraper and has had an extraordinary economic bearing on the design and construction of city buildings and the utilization of real estate for building purposes.

About the middle of the nineteenth century freight elevators or hoists of simple form in factories and warehouses and various crude devices in mines were utilized for vertical transportation of goods and materials, and for the most part were worked by belt-driven spur-gear machines operated by steam engines. In Europe hydraulic machinery had been extensively developed, and plunger machines, with a car mounted on the upper extremity of a vertical piston or plunger working in a hydraulic cylinder extending down into the ground, were employed for freight lifts, and also for passengers when the need for such transportation was realized. In the United States about 1870 various modifications of freight elevators were made adapting them for passenger service; and soon after a water-balance elevator was employed, where the supply of water in an iron bucket could be regulated at will and thus the motion of the car directed. By 1878 a vertical-cylinder hydraulic elevator was introduced into the Borel Building, New York City. This type of machine soon became standard, lending itself by degrees to increased range of operation and especially of height, so that the tall building of eight or more stories constructed up to the limits of height permitted by masonry walls was possible.

In the early hydraulic elevator a piston working in a vertical cylinder carried at its exterior extremity one or more pulleys, or sheaves, around which passed cables which were then bent around sheaves at the top of the elevator shaft and supported the car, running in guide rails. As water, under suitable pressure for

4. VERTICAL CYLINDER AND PISTON FOR HYDRAULIC ELEVATOR.
5. EXPRESS ELECTRIC ELEVATOR WITH DUPLEX MOTOR.

the work to be done and the size of the cylinder, was admitted to the latter, the piston was moved, and its motion, multiplied by the sheaves on the familiar principle of the block and tackle, was transmitted to the cables supporting the car. The weight of the car was counterbalanced by the moving parts of the piston and sheaves and partly by weights, and the control mechanism provided for the introduction of water on either side of the piston so that it could be moved in the desired direction. A reliable valve system regulated the quantity and pressure of the water, and the machine was soon developed to a degree where it was reliable and economical. With the opening of the skyscraper epoch, about 1893, when steel-frame construction made possible buildings of greatly increased height, the hydraulic elevator was developed to a point where it could not only satisfy the height of travel, but could reach a speed of from 400 to 800 feet per minute. The cylinder, instead of being placed vertically, as in the first and simplest types, could be mounted horizontally, usually in a basement or cellar, and a pulling or pushing motion of piston and sheaves communicated to the supporting cables, so that there was a saving of space and the possibility of using a higher gear, or ratio of travel of the piston to that of the car, by means of an increased number of moving pulleys, or sheaves. This will be appreciated when it is stated that a column of water greater in height than 32 feet, or the equivalent of the pressure of the atmosphere, could not be employed, so that for a building 240 feet in height, e.g., an eight to one gear was required.

For many years the hydraulic elevator enjoyed full supremacy and was, all things considered, an efficient and safe mechanism; but about 1893, with the growing use of electricity and its general availability for power, the electric elevator began to loom up as a formidable competitor to the hydraulic machine. Not only were increased heights of buildings to be considered, but the architects demanded, in addition, heavy and rapid traffic and economy of operation and maintenance cost. As increased capacity meant the increase of the size of the cylinders unduly for low pressures, installations were constructed where high-pressure machines working at from 100 to 800 pounds were used. Such plants met, in most cases, the conditions of service, but eventually it was found that the electric elevator was destined for universal employment.

As early as 1884 a machine worked by electric power had been invented and installed by W. Baxter, Jr., but the first installation that indicated a distinct type was in 1889, when a drum type of electric elevator was placed in a New York City building. Here the cable attached to the car, after passing over one or more sheaves, was wound around a drum, or windlass, revolved by an electric motor whose armature shaft carried a worm, or spur gear meshing into a larger gear wheel on the drum. The motor was controlled by resistances and other devices in the usual way, and the machine found wide application where light loads were involved and high speeds were not demanded. It was greatly improved and made available for various conditions of electrical supply, including both alternating and direct current, and obtained a wide range of operation from the heavy-capacity express service of the office build-

ing to the small passenger elevator of the private dwelling under the control of the passenger by means of a push button and simple automatic apparatus.

In addition to the drum type numerous other arrangements of electric motors were employed. The Sprague-Pratt multiple sheave system employed a motor where a screw connected with its armature was revolved in a traveling nut directly connected with a compound sheave by which the motion was magnified just as in the case of the hydraulic machine. The drum type was not found feasible where greater speed than about 400 feet per minute was required, as this meant too high a peripheral velocity for the drum, or windlass, around which the cable was wound, and made impossible the rapid acceleration of the car in starting from a floor and its proper retardation when stopping. The screw type did little better in the way of speed, while a system using two motors in a friction-drive arrangement attained a speed of 600 feet per minute, but had disadvantages in the way of economy and undue wear on the ropes. Consequently, with the necessity for increased

TRACTION ELEVATOR.

heights and increased speed, in order to make the twentieth and thirtieth stories of buildings accessible, more was demanded of the electric-elevator builders, as had been the case with the

designers of hydraulic machines, while at the same time simplicity and efficiency were also considerations which were figuring more than ever in the design and construction of buildings.

About 1904 the direct-traction elevator was developed by the Otis Elevator Company, and this, with modifications and improvements, has become almost standard, especially for tower buildings where a high lift is required. This machine resulted from the improvements in motor design and reliability, as its operation is based fundamentally on the control of a low-speed motor of high efficiency. Here the ropes, or cables, from the car pass over the driving sheave on the shaft of an electric motor usually placed at the top of the hatchway and then around an idler sheave, or pulley, below, and again around the driving sheave, so that each rope, having two half turns around the driving sheave, affords sufficient traction to drive the car and the counterweight, the latter being equal in weight to the car and its average load. The armature shaft is revolved when the current passes through the motor, and the car rises and the counterweight falls, or vice versa, depending upon the direction of revolution and the speed of the armature shaft, both of which, through the agency of magnetic devices, switches, and resistances, are at the command of the car operator at his lever. The speed of the car is equal to the peripheral velocity of the driving sheave over which the cables pass; and the greater the load in the car, the greater will be the adhesion between the ropes and the sheave. A brake, consisting of leather-faced shoes acting on a brake pulley under the influence of heavy helical springs, is electrically released when the car is in motion, holds the car at any point of rest, acting automatically when a safe speed is exceeded, or the car gets beyond the control of the operator, or reaches the limiting points of travel at the top and bottom of the shaft. The traction elevator has the important advantage of being economical in space, a vital consideration in a city office building, and, furthermore, its mechanism is marked by extreme simplicity.

The weight of the cable in itself is no small item, and it must be balanced by some form of chain, or flexible cable whose weight per linear foot is equal to that of the supporting cables. The traction elevator can be used for any height of rise, and successively it has been applied to such buildings as the Singer Tower, with a travel of 546 feet for the highest lift car, to the Metropolitan Life Insurance Company Tower, with a car travel of 586 feet, 5½ inches, and to the Woolworth Building, with 54 stories and a total height of 785 feet, where there is a lift of 679 feet, 10¼ inches—marking the record both for building height and for elevator installation in 1914.

Among the more efficient hydraulic machines are plunger elevators, which were developed to meet the increased heights and high speeds. Plunger elevators of limited travel had been used in Europe, but they had never acquired much vogue in America. However, with the means of drilling bore holes of considerable depth and straight in direction, an impetus was given to such installations, and elevators with a travel up to about 400 feet were installed. In the plunger elevator the plunger supporting the car is usually made of 6-inch steel tubing and is formed by lengths connected with internal

couplings. Within the plunger there is a steel rope connecting the cast-iron-bottom casting to the top, while there are four brushes that hold the bottom piece in the center of the cylinder. This cylinder in which the plunger moves up and down is also of steel tubing about 2 inches greater in diameter, and sunk in a well in the ground usually made 3 or 4 inches greater in diameter, and, where it passes through gravel or clay, lined with a retaining casing. Through a system of valves, varying in different types of machines, water under pressure is admitted to the cylinder, forcing the plunger up and out and raising the car. Permitting the water to escape from the cylinder allows the plunger to sink and the car to descend, the operator with his controlling device being able to give the necessary movement to the valves, usually through the medium of a pilot valve. The plunger elevator, like other types, must be counterbalanced, though, of course, the car and plunger will weigh more than the counterweight, as the descent is due to the action of gravitation.

The plunger elevator operates smoothly under ordinary conditions, is reliable and free from breakdowns or need of repairs, and supplies high speed for moderately high lifts. In one building in New York 21 such machines are in daily operation, seven of which are used for express service rising 368 feet to the twenty-sixth story.

Whatever the type of elevator, the fundamental considerations are ease of control and safety. The common method of control is a hand rope passing through the car, or a wheel or lever working on a system of standing ropes, or, in the case of an electric elevator, some form of switch worked by the operator. The hand rope may act directly on the main valve, or upon a pilot valve so that when the operator, when the car is at rest, pulls down on the rope, water is admitted to the hydraulic cylinder and the car rises. Grasping the rope, he causes it to move in the opposite direction, and the supply of water is cut off by the valve so that the car is stopped; while, if he moves the rope upward, the water is drawn from the cylinder, and the car descends. This device was crude and ineffective, so eventually the ropes were led around pulley wheels mounted on the outside of the car, the position of which could be varied by means of a lever, and the desired strain given to the ropes, and the valve moved as desired. The lever of the electric elevator, likewise, is only a switch to admit current to the motor and cause its armature to revolve, but here provision has to be made for properly and automatically regulating the amount of current by means of magnetic appliances and resistances. In the best switches the operator has at his command several rates of speed, and, if his hand is withdrawn from the lever, it automatically returns to the stop position, and the machine comes to rest.

From the very beginning, notwithstanding the responsibility of the elevator operator, designers realized that the possibility of accident must be faced, and various safety devices have been introduced, until to-day a number of these are essential to every machine. The fall of the car, due to the failure either of the cables themselves or their fastenings, or the machine getting beyond control on its downward journey, must be guarded against, and also an uncontrolled upward trip, where, after the car has

been violently stopped, the cables might be torn from their fastenings and the car suffer a fall. At first guides of hard wood in which chisel knives would engage when a certain determined rate of speed was exceeded were employed; and, later, various forms of clamps and wedges, which worked automatically and under the influence of powerful springs, would hold the car tight in its track. Often an automatic ball governor, mounted at the top of the hatchway and revolving by ropes connected with the car, is employed, which releases the wedges when the speed is too high, while in this and other types of safety device an emergency lever can be released by the operator to set the brakes. In many electric elevators the power is also cut off by the action of the governor. Furthermore, there is an air-cushion arrangement whereby the lower part of the shaft is inclosed, so that a falling car could be brought to rest on the cushion of compressed air produced by its downward motion. Other air-cushion arrangements are employed where projections from the car engage cleats on cables which are connected with pistons and air cylinders.

In the traction elevator spring and oil-compression buffers are placed under both car and counterweight, and have proved effective in actual tests where in the highest hoistways all other safety devices have been cut out, and the machine allowed to descend uncontrolled and brought to rest effectively and without damage. The car or the counterweight accordingly strikes the piston of the buffer, which, acting on springs and oil-filled cylinders, telescopes and drives the oil from one chamber to another, thus absorbing the shock completely. An additional safety device found on many elevators consists of parallel wire ropes, extending vertically the length of the hoistway, which carry transversely cross pieces through which the ropes pass in an oblique direction, while upon the frame of the car there are cams which upon undue velocity are forced out and catch on cross pieces acting to retard the motion of the car. There are, in addition, various limiting valves and stops and various electrical devices such as indicators, telephones, door-closing and other mechanisms, all of which aim to facilitate the operation of the apparatus.

Some of the more notable elevator installations in the United States are as follows: in New York City, the Woolworth Building, with 26 elevators; the Metropolitan Life Insurance Building, with 30 elevators; the Hudson Terminal Building, with 50 elevators; the City Investing Building, 21 elevators; the Whitehall Building, with 29 elevators, and the Municipal Building, with 30 elevators. The Rothschild Building, in Chicago, has 30 elevators; the Insurance Exchange Building, 16 elevators; the Peoples' Gaslight and Coke Company Building, 14 elevators; and, in Seattle, Wash., the L. C. Smith Building has 8 elevators.

Previous to the completion of the high-tower buildings in New York City, the elevator in the Washington Monument, with a travel of 500 feet, and those of the Eiffel Tower (q.v.), with a travel of 526 feet, were noteworthy as regards height. Elevators have also been built for carrying heavy loads, such as at the Weehawken and Jersey terminus of the North Hudson County Railway, where cars held 140 people each for a lift of 148 feet; while in tunnels under the Elbe at Hamburg and under the

Clyde at Glasgow wagons are also transported from the streets to the level of the tubes.

Escalator. Closely allied with the elevator is the escalator, or moving stairway. This gives access from one floor or level to another by continuous action without the necessity for operators or for opening and closing doorways, etc. Escalators are employed where a large number of people must be transported, as in department stores, railway terminals, subways and elevated railway stations, and at amusement pavilions. They consist of endless chains operated usually by electric motors and supporting a series of parallel links forming a treadway, or of treads and risers which at the beginning and end of the ascent take a flat or horizontal position, but, as soon as the incline is reached, arrange themselves as treads and risers like those of an ordinary stairway. The moving platform fits closely within the floor proper and moves so slowly that it is approached without difficulty by persons of usual agility. It carries a moving hand rail to support passengers in making the ascent. At the top there may be a diagonal partition and usually an attendant to facilitate the exit on to the solid floor. The chief advantages of the escalator are its simplicity and the vast number of people that can be handled, as it serves to keep the flow of traffic always and continuously in one direction.

Bibliography. For an historical discussion of American passenger elevators, see Brown, "Passenger Elevators," in *Transactions of the American Society of Civil Engineers*, vol. liv, part B (1905). For general discussion of electric elevators, see *Transactions of the American Institute of Electrical Engineers* (especially vol. xix, 1902). Consult also: Baxter, *Hydraulic Elevators: Their Design, Construction, Operation, Care, and Management* (New York, 1910); Cullmer and Bauer, *Elevator Shaft Construction* (ib., 1912); Swingle, *Elevators, Hydraulic and Electric: A Complete Handbook Designed for the Use of Engineers and Operators* (Chicago, 1910); Bolton, "Operation of Passenger Elevators," in *Transactions of the American Society of Civil Engineers*, vol. lxiv (New York, 1909); id., "Operating Conditions of Passenger Elevators," *Journal of the American Society of Mechanical Engineers*, vol. xxxii (New York, 1910). The current issues of the various engineering journals furnish descriptions of the more notable elevator plants as they are installed, while the larger manufacturing companies publish considerable advertising material that has technical value also. See ACCUMULATORS.

ELEVEN THOUSAND VIRGINS, THE. See URSULA, SAINT.

EL-FASHER, ʔl-fa'shēr. The capital of Darfur (q.v.), Egyptian Sudan, Africa, situated in a well-watered valley east of the Marrah Mountains (Map: Africa, G 3). Owing to its position at the point where some of the most important caravan routes of northeastern Africa meet, the town is of considerable commercial importance. Its permanent population is estimated at 4000.

EL-FAYUM. See FAYUM.

ELF OWL. The smallest of American owls, and perhaps the smallest of all owls—*Micropallus whitneyi*. It is little more than 6 inches in length and is reddish gray above and white below, barred irregularly with rufous brown. It dwells in and about Arizona, feeds mainly upon beetles and grasshoppers, and keeps itself

in thickets or willow copses, nesting almost invariably in deserted woodpeckers' holes made in the giant cactus. Consult: Fisher, *Hawks and Owls of the United States* (Washington, 1893); Beebe, *Owls of the Nearctic Region* (New York, 1907); and the *Auk*, vol. iii (ib., 1886).

ELGAR, SIR EDWARD WILLIAM (1857-). An English musician, born at Broadheath, near Worcester, June 2, 1857. He was educated at Littleton House and studied the violin and the organ. In 1882 he became conductor of the Worcester Instrumental Society and in 1885 succeeded his father as organist at St. George's. Both of these positions he gave up in 1889 and two years later began to devote himself entirely to composition. His earlier works—*The Black Knight* (cantata, 1892); *Lux Christi* (oratorio, 1896); *Choral Suite, from the Bavarian Highlands* (1895); *Te Deum* (1897); *Caractacus* (1898); and *Orchestral Variations* (Enigma Variations) (1899)—gradually brought his name into prominence, so that for the Birmingham Festival of 1900 he was commissioned to write an oratorio, *The Dream of Gerontius*. Its first production in England (1900) aroused no great enthusiasm, but when the work was heard at the Niederrheinische Musikfest in 1902, and Richard Strauss spoke of it in terms of highest praise, it immediately was taken up again in England and met with phenomenal success. Since then Elgar has been considered the foremost of living English composers, although in none of his subsequent compositions does he rise again to the height of such genuine inspiration. His most ambitious work is an oratorio trilogy, of which two parts only are completed, *The Apostles* (1903) and *The Kingdom* (1906). Other works in the larger forms are: two symphonies (A♭, 1908, and E♭, 1911); three concert overtures, *Froissart* (1890), *Cockaigne* (1901), *In the South* (1903); and a violin concerto (1910). In 1904 Elgar was knighted. From 1905 to 1908 he was professor of music at the University of Birmingham. In 1906 he visited the United States, conducting his *Apostles* at the Cincinnati May Festival. Consult R. J. Buckley, *Sir Edward Elgar* (New York, 1905), and E. Newman, *Edward Elgar* (London, 1906).

EL-GHOR, ʔl-gôr', WADI. The northern part of the great depression known as El-Araba, which extends from the base of Mount Hermon to the Gulf of Akabah. The length of El-Ghor from the Sea of Galilee to the Dead Sea is about 65 miles, and its width varies from 6 to 12 miles.

ELGIN, ɛl'gin. A royal burgh, capital of Elginshire, or Morayshire, Scotland, on the Lossie, about 5 miles from its seaport, Lossiemouth, on the Moray Firth, and 71 miles northwest of Aberdeen (Map: Scotland, E 2). Its once magnificent cathedral, partly of Early English and partly of Middle Pointed architecture, dedicated to the Holy Trinity, begun by Bishop Andrew Moray in 1224, is now a ruin. The castle, styled of old the manor of Elgin, whose ruins, surmounted by an obelisk—erected to the memory of George, fifth and last Duke of Gordon—crown the Lady Hill, was a residence of the earls of Moray, for some time superiors of the burgh. Among the modern buildings are Gray's Hospital, Anderson's Institution, county buildings, courthouse, and asylum. Pop. (royal burgh), 1901, 8407; 1911, 8656. About 2 miles north of the town on the edge of Loch Spynie are the remains of the strongly fortified palace

of the bishops of Moray; and 6 miles to the southwest in a beautiful valley are the picturesque ruins of the Cistercian Pluscarden Priory, founded about 1230. Elgin was probably a royal burgh as early as the reign of King David I (1124-53) and had its privileges confirmed by several of his successors.

ELGIN, ɛl'jin. A city in Kane Co., Ill., 37 miles west by north of Chicago, on the Chicago, Milwaukee, and St. Paul and the Chicago and Northwestern railroads, and on the Fox River (Map: Illinois, H 1). The city is in a fertile agricultural region and is the centre of extensive dairy and ice industries. It has numerous manufacturing plants, which include well-known watch factories, condensed-milk works, a silver-plate factory, a shirt factory, a watchcase factory, shoe factories, machine shops, foundries, flouring mills, etc. In the city are the Elgin Academy, a Roman Catholic seminary, and the Northern Illinois Hospital for the Insane, accommodating 1800 patients. There are also two hospitals, a public library, and a system of parks. Elgin was settled in 1835, was chartered as a city in 1854, and adopted the commission form of government in 1912. The water works are owned and operated by the municipality. Pop., 1890, 17,823; 1900, 22,433; 1910, 25,976; 1914 (U. S. est.), 27,485.

ELGIN, ɛl'gin, THOMAS BRUCE, seventh EARL OF (1766-1841). An English diplomat. He was educated at Harrow, Westminster, St. Andrews University, and in Paris; succeeded to the earldom of Elgin and Kincardine in 1771; entered the army in 1785, and rose to the rank of major general. In 1790 he began his diplomatic career as a special envoy to the Emperor Leopold II. In 1792 he was made Minister at Brussels, and in 1795 Envoy Extraordinary at Berlin. From 1799 to 1802 he was English Ambassador to the Ottoman Porte, and it was while occupying this position that he began gathering the collection known as the Elgin Marbles (q.v.), purchased by the government for the British Museum in 1816. He was a representative peer from Scotland from 1790 to 1840.

ELGIN, eighth EARL OF, and **KINCARDINE**, twelfth EARL OF, JAMES BRUCE (1811-63). A British diplomat and statesman, the son of the preceding. He was born in London and was educated at Eton and Oxford. In 1841 Southampton elected him a Liberal-Conservative member of Parliament; but as his father died the same year, he succeeded to the Scottish peerage, which excluded him from the House of Commons without admitting him to the House of Lords. He began his official career at the age of 30 as Governor of Jamaica, and was Governor-General of Canada from 1847 to 1854. In Jamaica he accomplished much for the education of the negroes and the improvement of agriculture. In Canada his instructions were to carry into effect the principle of responsible government, a task which harmonized with his own political convictions. He governed by the advice of his ministers, and during his term of office responsible government was finally established and accepted. Nevertheless he met strong opposition from the Conservatives, and on the occasion of his signing the measure known as the Rebellion Losses Bill (see CANADA, *History*) his carriage was stoned and the Parliament buildings at Montréal were burned. By the Reciprocity Treaty of 1854-66 Elgin secured free trade between Canada and the United States in the

natural products of the farm, the forest, the mine, and the sea. British subjects and American citizens shared equally the coast fisheries of the provinces, the navigation of the St. Lawrence, the Canadian canals, and Lake Michigan. In 1849 he was admitted to the English peerage as first Baron Elgin. In 1857 he proceeded to China with an army, as special envoy to demand reparation for the illegal seizure of a British vessel. At Point de Galle he heard of the Indian Mutiny and without hesitation diverted his army to the assistance of Lord Canning, who with his help was enabled to hold out until reinforcements arrived. The mission to China was delayed, but eventually Lord Elgin arrived there, and the Tientsin Treaty was consummated in 1858. He also secured concessions from Japan by the Treaty of Yeddo. On his return to England he was appointed Postmaster-General and elected lord rector of Glasgow University; but as the Chinese refused to ratify their treaty, he went back to China and with a combined force of English and French captured Peking (in 1860) and this time concluded a satisfactory convention, which regulated the Chinese relations with the West down to 1890. In 1862 Lord Elgin became Viceroy of India, but in 1863 he died. Consult: Walrond (ed.), *Letters and Journals of James, Eighth Earl of Elgin* (London, 1872); Loch, *Personal Narrative of Occurrences during Lord Elgin's Second Embassy to China, 1860* (ib., 1869); Oliphant, *Narrative of the Earl of Elgin's Mission to China and Japan in the Years 1857-58-59* (New York, 1860); Stephen, *Dictionary of National Biography*, vol. vii, by Arbuthnot; Kaye, *Life of Lord Metcalfe* (London, 1858); Bourinot, *Lord Elgin* (Toronto, 1903). See also INDIA.

ELGIN AND KINCARDINE, VICTOR ALEXANDER BRUCE, ninth EARL OF (1849-). An English statesman, born at Monklands, near Montreal. He succeeded his father in 1863, studied at Eton and at Balliol College, Oxford, and became, in 1886, Treasurer of the Household and First Commissioner of Public Works. From 1894 to 1899 he was Governor-General of India, in 1904 headed the Commission on the Scottish Church Crisis, and from December, 1905, to April, 1908, was Colonial Secretary in the Campbell-Bannerman ministry.

ELGIN MARBLES. A celebrated collection of ancient sculptures, brought from Greece by Thomas, seventh Earl of Elgin, and acquired from him for the British Museum. On his appointment as Ambassador to the Porte in 1799, Lord Elgin prepared to have drawings and casts made of the Athenian sculptures, but he was hindered until, in 1801, he secured a new firman, giving him enlarged powers and particularly forbidding any hindrance to his "taking away any pieces of stone with inscriptions or figures." After a year of toil the principal figures from the pediments of the Parthenon, 15 from its metopes and 56 slabs from the frieze, one of the so-called Caryatids from the Erechtheum, part of the frieze of the temple of Athene Nike, and numerous fragments and inscriptions, had been prepared for shipping. The war with France delayed the shipment, and it was 1812 before the last consignment arrived. Strange as it now seems, the Elgin Marbles were at first received coldly and even with severely hostile criticism, and it was not till such recognized authorities as Ennio Quirino Visconti and Canova had pointed out their historical and artis-

tic value that in 1816 a committee of the House of Commons was appointed to consider their purchase by the government. Lord Elgin had already spent £51,000, besides the loss of interest, which he estimated at £23,240. The hearing proved the legality of his title to the marbles, and the testimony of many artists confirmed the favorable judgments of the foreign critics, so that the committee reported to the House on June 7, 1816, in favor of their purchase for £35,000. The attacks upon Lord Elgin were by no means confined to the criticism of his marbles. His act in removing the marbles was denounced violently as vandalism of the most flagrant kind, and the wrath of Lord Byron found expression in Child Harold's lament over "The walls defaced, the moldering shrines removed by British hands." There can be no doubt that in the removal of some of the metopes Elgin's workmen had wrought considerable damage to what still remained of the Parthenon, after the explosion of 1687; but a large part of the sculptures were not in place, and those that had not fallen were a mark for the wanton destructiveness of the Turkish garrison. The accounts of contemporary travelers and the present condition of what was left behind show very plainly what would have been the fate of these masterpieces had they not been rescued. The Turks had already used many fragments in the walls of the Acropolis and of private houses, and a considerable mass of marble had only recently been burned to furnish lime for mortar. Consult: Michaelis, *Der Parthenon* (Leipzig, 1871); id., *Ancient Marbles in Great Britain*, trans. by Fennell (Cambridge, 1882); *Ancient Marbles in the British Museum*, vols. vi-ix (London, 1830-39, 1842); A. H. Smith, *Catalogue of Sculpture in the Department of Greek and Roman Antiquities* (ib., 1900). For the subjects of these sculptures, see **PARTHENON**; for their place in the history of Greek art, see **GREEK ART**.

ELGINSHIRE, ɛl'gɪn-shɪr, **MORAYSHIRE**, or **MURRAYSHIRE**. A maritime county in the north-eastern part of Scotland (Map: Scotland, E 2). Area, 476¾ square miles. In the south the high and rugged Monadhliadh of Inverness-shire divide the basin of the Spey and Findhorn. The soil is very fertile in the north, and the county is noted for its advanced state of agriculture. It has profitable salmon and salt-water fisheries. Its principal industry is the manufacture of whisky. Chief town, Elgin. Pop., 1801, 27,760; 1851, 39,000; 1901, 44,800; 1911, 43,427.

EL GRECO. See **GRECO**, **EL**.

EL-HASA, ɛl-hä'zä. A tributary state of Turkey, included in the Turkish Vilayet of Basra, on the east coast of Arabia (Map: Turkey in Asia, F 5). The region is noted for its excessive aridity. Its surface is generally flat and sandy, with here and there an oasis. The inhabitants, who number about 175,000, are chiefly engaged in raising camels and in cultivating dates, indigo, cotton, and wheat. Capital, El-Hofuf (q.v.). The territory has been a dependency of the Ottoman Empire since 1810.

EL-HOFUF ɛl-hö'fuf, or **HOFHUF**. The capital of El-Hasa, Arabia, near the Persian Gulf (Map: Turkey in Asia, F 6). Its seaport is El-Ajr. It has an estimated population of over 25,000.

ELHORST, ɛl'hɔrst, **HENDRIK JAN** (1861-). A Dutch Old Testament scholar, born in

Wisch, Guelderland, and educated at the University of Amsterdam. He entered the Mennonite ministry and held positions in Insuum, Friesland (1887), Arnhem (1888), and The Hague (1898), and Haarlem (1900), where he was a prominent member of Teyler's Foundation for the study of theology, etc., and in 1906 became professor of Hebrew language, antiquities, and literature in the University of Amsterdam. In 1911 he received the degree of D.D. from the University of Aberdeen. He published critical commentaries (with translations) on Micah (1891) and Amos (1899), and *Israel in het licht der jongste onderzoekingen* (1906).

ELI (Heb. *'Eli*, elevation). A priest and, according to the biblical account, also one of the judges of the Hebrew confederacy. He traced his family back to Ithamar, the youngest son of Aaron (cf. 1 Chron. xxiv. 3 with 2 Sam. viii. 17 and 1 Kings ii. 27), and officiated in the temple at Shiloh. Eli was also judge over Israel for 40 years (1 Sam. iv. 18; the Greek version has "20 years"). The boy Samuel was brought up in the temple under his care (1 Sam. ii. 11, 21). Eli's two sons, Hophni and Phinehas, were guilty of serious misconduct (1 Sam. ii. 12-17, 22), for which Eli reproved but did not punish them (1 Sam. ii. 23-25). For this neglect Yahwe censured him, telling him, first through "a man of God" (1 Sam. ii. 27-36) and then through the youthful Samuel (1 Sam. iii. 11-18), that his house should be punished for its wickedness. This promise was executed in the battle of Ebenezer (1 Sam. iv. 1, 10-11), when Hophni and Phinehas were slain and the ark of God taken by the Philistines. When Eli, then 98 years old, heard the news, he fell backward from his seat and died (1 Sam. iv. 15, 18). The priesthood finally passed out of the house of Ithamar in the days of Solomon (1 Kings ii. 27).

ELIA. See LAMB, CHARLES.

ELIAS, APOCALYPSE OF. See APOCRYPHA, section *Old Testament*.

ELÍAS, á-lé'as, DOMINGO (1805-67). A Peruvian statesman. He was born at Ica, Peru, and was educated at a college at Madrid and in France. Returning to Peru in 1825, he became an enthusiastic supporter of liberal and progressive principles. One of his most noteworthy achievements was the introduction of the planting of cotton on a large scale into the new republic. The introduction of the vine and the introduction of Chinese labor were also due to him. He established at Lima the College of Our Lady of Guadalupe and several other educational institutions and afterward played a conspicuous part as a soldier and legislator.

ELIAS, é-lí'as, NEX (1844-97). An English explorer and diplomat, born at Widmore (Kent). In 1865 he became a fellow of the Royal Geographical Society, in 1866 went to Shanghai, China, as the employee of a mercantile firm, and in 1868 set out upon an expedition for the examination of the new and old courses of the Hoang-ho. In 1872 he undertook a difficult journey of 4800 miles across the Gobi Desert to Nizhni Novgorod. The results of this expedition were described by him in a paper written for the Royal Geographical Society, from which he received a gold medal. He was appointed extra attaché to the Foreign Office at Calcutta in 1874, shortly afterward assistant to the British resident at Mandalay, and in 1877 an attaché to the mission at Kashgar. Later he was variously detailed for special duty, and from 1891 until

his retirement in 1896 was Consul General for Khorasan and Seistan. In 1885 he began a survey from the Chinese boundary to Ishkashim (a distance of 600 miles). During this expedition he contributed much to the determination of the geography of the Pamirs and decided the Panja River to be the upper course of the Oxus, or Amu-Daria. His writings include chiefly papers in the journals of the Royal Asiatic Society and the Royal Geographical Society, and an English version of the *Tarikh-i-Rashidi* of Mirza Haidar (with E. D. Ross, 1897).

ELIAS LEVITA. See LEVITA.

ÉLIE DE BEAUMONT, á-lé' de bó'môn', JEAN BAPTISTE ARMAND LOUIS LÉONCE (1798-1874). A French geologist. He was born at Canon (Calvados) and educated at the Ecole Polytechnique and the Ecole des Mines in Paris. In 1823 he accompanied Dufrenoy and De Villiers on a scientific tour of England and Scotland. Many of the scientific observations made during this journey were embodied in the volume *Voyage métallurgique en Angleterre* (1827), of which Elie de Beaumont and Dufrenoy were joint authors. Elie de Beaumont was one of the founders of the geological survey of France and rendered valuable services in the publication of maps and descriptions of the geology of that country. He also made an exhaustive study of mountains, and it is in this connection, perhaps, that his name is best known to scientists. While his theory that mountain ranges of the same orientation are contemporaneous and formed by the same causes did not meet with general acceptance, it was the means of attracting increased interest to this branch of geology. In its support he also collected and published much new information. In 1829 he was made professor of geology at the Ecole des Mines, and in 1835 he became a member of the Academy of Sciences. On the death of Arago (1853) he was selected to serve as perpetual secretary of the Academy. He was elected to membership in many foreign scientific societies, including the Academy of Berlin and the Royal Society of London. In 1852 he became, by decree, a Senator of France. His best-known works are *Leçons de géologie pratique* (1847) and *Notice sur le système des montagnes* (1852).

ELIGIUS, é-lí'í-ús, SAINT, also called ELOI, or ELOYSIUS (c.588-659). An artist and bishop of early France, the patron saint of goldsmiths. He was born near Limoges, about 588. He learned the goldsmith's trade, was introduced at the court of Clotaire II, and became Master of the Mint under that King and his son and successor, Dagobert I (628-38). Both kings trusted him with important works, among them a chair of gold. He also made shrines, ornaments for tombs, sarcophagi, etc. Eligius was a faithful and conscientious servant of his masters and showed a strong inclination to piety. He gave liberally to the poor, founded religious houses, and was active against heretics. In time he became a priest, and in 640 was made Bishop of Noyon. After settling the affairs of his diocese in order, he made a missionary visit to the heathen of Flanders and Zeeland. His life and works are in Migne, *Patrologia Latina*, lxxxvii.

ELIHU, é-lí'hū or é-lí'hū. One of the speakers in the Book of Job. In the prose introduction to his four speeches, which occupy chaps. xxxii-xxxvii, he is said to be a son of Barachel,

the Buzite, of the family of Ram. The fact that his name does not occur among the friends of Job in the old prose story preserved as a prologue and an epilogue to the work indicates that the section ascribed to Elihu is a later supplement to the dialogues. This conclusion is amply sustained by the internal evidence. Though the author appears with an air of superior knowledge, as if a new solution of the riddle were to come from his lips, his arguments are precisely the same that have already been urged by the three friends. Even his language is reminiscent of their speeches. The most incisive and sympathetic criticism cannot make of the chapters a real contribution to the discussion or a work worthy of the pen of that inspired poet to whom we owe the dialogues. Only in his angelology does the author show a certain originality; but his views on that subject have no bearing on the great arguments of the book and clearly betray his later date. The weight of scholarly opinion is strongly against the authenticity of these speeches. Such critics as have recently attempted their rehabilitation have been largely influenced by the manifest possibility of greatly improving the text by conjectural emendation. ELIJAH (Heb. *Eliyāhū*, Yahwe is God; in the Greek form, occurring in the New Testament, *Ἠλίας*, *Elias*). An Israelitish prophet. The story of Elijah is elaborately told, chiefly in connection with the reign of Ahab (1 Kings xvii-xxi), but also in connection with that of Ahab's successor, Ahaziah (2 Kings i-ii). This narrative is probably based, as is also the story of Elisha, on separate literary sources which lay before the compiler of Kings, and which contained a series of stories with legendary embellishments of the earlier prophets and seers that have been rather skillfully woven into the narrative of the kings of Israel and Judah. Elijah, whose home appears to have been in Gilead (though the reading 1 Kings xvii. 1 is not certain), may be designated as a devotee of Yahwe, who resented the . . . of the Yahwe cult with the worsh . . . antitish Baalim (see BAAL), and whose fierce opposition was brought to a climax by Ahab's readiness, for political reasons, to introduce the cult of the Tyrian Baal into the domain of Israel. He represents the opposition to all Baal worship brought to a focus through the step taken by Ahab in building a temple to Baal of Tyre as a symbol of the alliance between Israel and the Tyrian kingdom that was brought about by the marriage of Ahab with Jezebel.

Elijah is rather abruptly introduced by the writer as the uncompromising opponent of Ahab, to whom he declares that no rain or dew is to fall save at the prophet's declaration. A famine ensues, during which time Elijah is miraculously fed by ravens. The famine increases, and at last Ahab is forced to yield and give his consent to a contest between Elijah and the prophets of Baal. The latter call upon Baal to send down the rain, but in vain. When Elijah, however, appeals to Yahwe, lightning comes to consume the bullock which the prophet had placed on an altar soaked with water. By

the order of Elijah the prophets of Baal are slain at the brook Kishon, and rain is sent by Yahwe. Such is the general character of the Elijah stories, all intended to illustrate the superiority of Yahwe over other gods. Ahab is represented as again led astray by Jezebel, who continues the opposition to Elijah. At times the latter is portrayed nigh unto despair; but he is encouraged by Yahwe, who appears to him in the "rustling of the breezes," and while threatening destruction to Israel promises escape to those who do not bow the knee to Baal. Even though the story of his life as given in the Bible be considered as having legendary and mythical features, we see in Elijah one of the most striking figures in Hebrew history—one whose attitude foreshadows important changes in the religious life of the people. He shares, however, many of the characteristics of the old-time seer, whose chief function it was to give oracles and to control the moods of the deity in whose service he stood. He wears a primitive dress—a robe of goat's or camel's hair with a leathern girdle. He is accompanied often by a guild of prophets, though at times he mysteriously disappears and seeks the solitude of the wilderness. So, during the great famine, it is in the wilderness that ravens bring him bread and meat every morning and evening, and it is again in a solitary spot of the wilderness beyond Beersheba that his strength is miraculously restored to him through a cake and a cruse of water that suddenly appear and which sustain him for 40 days. He is not connected with any sanctuary and holds no position at the court. His appearance is as sudden as his disappearance. His courage is unbounded, for those parts of the narrative which picture him denouncing King Ahab probably rest upon historical ground, even though details have been added to color the dramatic situation. (See AHAB; JEZEBEL.) The transfiguration of Elijah, which takes place in the presence of his disciple Elisha (2 Kings ii. 11), may be a strange touch illustrating the admixture of myth and legend. A fiery chariot with fiery steeds descends from above, and Elijah rides in the storm to heaven. An old storm myth, in which the rolling of the clouds is taken as portraying the storm god himself riding in his chariot, may have been incorporated into the story of the old prophet. The mantle of Elijah falls from him as he ascends, and it is picked up by Elisha. In this way the indication is given that Elisha is to continue the work of Elijah. See ELISHA. ELIJAH OF WILNA. See WILNA, RABBI ELIAS.

ELIMINANT. See DETERMINANTS; ELIMINATION.

ELIMINATION (from Lat. *eliminare*, to turn out of doors, from *ex*, out + *limen*, threshold). A process by which, from a number of statements concerning several quantities, a separate statement concerning each is obtained. In a larger sense it means the setting aside of

all extraneous considerations—of everything not essential to the result. In algebra elimination is the operation which causes a quantity or a letter common to two or more equations to disappear, thus reducing a given system of equations to one of a less number of unknowns. If three unknown quantities, e.g., are to be found from three independent equations, the first step is to form from the three given equations two new ones, so as to eliminate one of the unknown quantities. From these two equations another of the unknown quantities is eliminated, giving one equation of one unknown quantity, the value of which is then found. In solving simultaneous linear equations, the simplest methods are those of addition (or subtraction) and comparison (or substitution). In the former method the coefficients of the unknown to be eliminated are made alike, or alike except in sign, and the two equations subtracted or added member to member, thus causing the unknown to disappear. In the latter case each equation is solved for the chosen unknown in terms of the other unknowns, and these expressions for the same quantity equated one to another. In complicated equations elimination becomes difficult and often impossible. Two methods for eliminating a single unknown from two consistent equations of any degree deserve special mention. The first, known as Sylvester's dialytic method, will best be understood from an example:

To eliminate x from the equations

$$\begin{aligned} a_3x^3 + a_2x^2 + a_1x + a_0 &= 0 \\ b_2x^2 + b_1x + b_0 &= 0 \end{aligned}$$

Multiplying the members of the first equation by x , and those of the second by x and x^2 successively, we have

$$\begin{aligned} a_3x^3 + a_2x^2 + a_1x + a_0 &= 0 \\ a_3x^4 + a_2x^3 + a_1x^2 + a_0x &= 0 \\ &\quad b_2x^2 + b_1x + b_0 = 0 \\ &\quad b_2x^3 + b_1x^2 + b_0x = 0 \\ b_2x^4 + b_1x^3 + b_0x^2 &= 0 \end{aligned}$$

The eliminant of these five equations in x^4, x^3, x^2, x is

$$\begin{vmatrix} 0 & a_3 & a_2 & a_1 & a_0 \\ a_3 & a_2 & a_1 & a_0 & 0 \\ 0 & 0 & b_2 & b_1 & b_0 \\ 0 & b_2 & b_1 & b_0 & 0 \\ b_2 & b_1 & b_0 & 0 & 0 \end{vmatrix} = 0$$

(See DETERMINANTS.)

This method may be applied to certain systems of more than two equations. Euler also suggested an ingenious method, as follows:

Given the equations

$$\begin{aligned} F(x) &= a_3x^3 + a_2x^2 + a_1x + a_0 = 0 \\ f(x) &= b_2x^2 + b_1x + b_0 = 0 \end{aligned}$$

These equations, being consistent, have a common root, r . Hence,

$$\begin{aligned} \frac{F(x)}{x-r} &= a_2x^2 + a_1x + a_0 \\ \frac{f(x)}{x-r} &= \beta_1x + \beta_0 \end{aligned}$$

Dividing these equations member for member and equating the coefficients of like powers of x , five equations are found, whose eliminant is the same as that given above. Theory of Algebraic Equations (New York, 1903); Young, *Monographs on Modern Mathematics* (ib., 1911); Fourier, *Die Auflösung der bestimmten Gleichungen* (Ger. ed. by Louvy, Leipzig, 1902).

ELÍO, á-le'ô, FRANCISCO JAVIER (1767-1822). A Spanish general. He was born at Pamplona and was educated at the Military Academy of Puerto Santa María. He fought with distinction in the wars in northern Africa and in the campaign with France (1793-1795) and on Sept. 9, 1807, recaptured Montevideo from the English and became governor of the city. Recalled to Spain in 1812, he became commander of the army of Catalonia and Valencia, and was afterward (1813) appointed Governor and captain general of Murcia and of Valencia. He had scarcely begun his service when the Count of Cervelló, the oldest general in Valencia, received an order from the King for the arrest and execution of Elío within 24 hours. Despite the fact that the order was signed by the ministers, it was so incredibly unjust that the Count of Cervelló, in agreement with three other generals, decided to postpone carrying out the instructions. The next day Elío received an autograph letter from the King so eulogistic that there could be no doubt that the order was a forgery. Elío believed it to be the work of the secret societies among the Liberals, and he became their uncompromising enemy. After peace and order, he did everything to promote the interests of the Kingdom of Valencia and Murcia, aiding labor, arts, beautifying Valencia City, irrigating works and otherwise improving agriculture, and introducing vaccination. Despite all this, as a consequence of his opposition to the Liberals, the storm burst upon him in 1822, and he was captured after the reestablishment of the constitution of 1812 and imprisoned by the insurgents in the citadel, where, upon an attempt of the soldiery to effect his release, he was brought before a popular tribunal, sentenced to death, and executed. He died protesting his fidelity to his sovereign, who later decreed to his widow and children all the emoluments of the dead general and created his oldest son Marqués de la Lealtad.

ELIOCROCA. See LORCA.

ELIOT, SIR CHARLES NORTON EDGEUMBE (1864-). An English Orientalist and educator. He was educated at Cheltenham and at Balliol College, Oxford, and became a fellow of Trinity College, Oxford. In 1888-1904 he was in the British diplomatic service—at St. Petersburg, Constantinople, Morocco, Bulgaria, Serbia, Washington (1898, Secretary of Embassy), Samoa, and (1900-04) Zanzibar, and the East African protectorate. In 1905-12 he was vice chancellor of the University of Sheffield, and in 1912 he was chosen to be the first principal of the University of Hongkong. He wrote papers on marine zoölogy and published: *A Finnish Grammar* (1890); *Turkey in Europe* (1900); *The East Africa Protectorate* (1905); *Letters from the Far East* (1907).

ELIOT, CHARLES WILLIAM (1834-). An American educator of note. He was born in Boston, Mass., graduated at Harvard College in 1853, was tutor in mathematics there from 1854 to 1858, and was assistant professor of mathematics and chemistry in the Lawrence Scientific School of Harvard from 1858 to 1863.

The years 1863-65 he passed in Europe in the study of chemistry and in the investigation of educational methods, and from 1865 to 1869 he held the chair of analytical chemistry in the Massachusetts Institute of Technology, then newly founded. In 1869 he became the twenty-second president of Harvard. His accession marked an epoch in the history of the institution. He forthwith began a remodeling of the curriculum on a liberal basis, broadly patterned after that of European universities. The elective system as known to American education was devised by him. His aim was to make this system, as conducted at Harvard, not less strict in its requirements, but more inclusive in its privileges, than that traditionally associated with the American college. He became an acknowledged authority on higher education, and his annual reports have been regarded as important in the study of problems connected with the subject. He also became widely known as an occasional speaker and a writer on educational and other topics. He retired from the presidency of Harvard University in 1909 and thereafter devoted himself to the cause of international peace. He was made an officer of the Legion of Honor and a grand officer of the Crown of Italy, received the Imperial Order of the Rising Sun (first class) and the Royal Prussian Order of the Crown (first class) in 1909, and was elected a corresponding member of the Academy of Moral and Political Sciences of the French Institute, a fellow of the American Academy of Arts and Sciences, and honorary president of the National Conservation Association. In 1913 he declined the ambassadorship to Great Britain, offered him by President Wilson. In 1914-15 he was president of the American Association for the Advancement of Science. His publications include: *The Compendious Manual of Qualitative Chemical Analysis* (with F. H. Storer, 1869; 16th ed., as revised by Nichols and re-revised by Lindsay, 1892); *The Working of the American Democracy*, an address (1888); *American Contributions to Civilization, and Other Essays* (1897); *Educational Reform: Essays and Addresses* (1898); *More Money for the Public Schools* (1903); *John Gilley* (1904); *Four American Leaders* (1906); *The Durable Satisfaction of Life* (1910).

ELIOT, GEORGE (1819-80). The pseudonym of Mary Ann Evans, generally recognized as the foremost of English women novelists. The Evans family, originally Welsh, was of sturdy, middle-class stock. Her grandfather, George Evans, was a carpenter and builder in Derbyshire. Her father, Robert, bred to the same business, seems to have been a man of uncommon vigor, both physical and mental, with an inborn knowledge of valuations that won him high repute as a land agent. In this capacity he was engaged by Mr. Francis Newdigate to take charge of his Arbury estate in Warwickshire, and here, at South Farm, George Eliot, the third child by his second wife, was born, Nov. 22, 1819, in the heart of that stolid farming life of the English midlands which she was later to mirror back so faithfully. The details of the author's early years, her companionships, her physical surroundings, and mental growth, might easily be filled in from her writings, since few novelists have drawn so freely from their own personal and intimate experiences. The chief landmarks of the neighborhood can readily be identified in

her earlier volumes. Arbury Court is the "Cheverel Manor" of *Mr. Gull's Love Story*; the town of Nuneaton is the "Milby" of *Janet's Repentance*; and its suburb, Chilvers Coton, figures as "Shepperton" in *Amos Barton*. Her family are admittedly the prototypes of the Dodsons in *The Mill on the Floss*; there is much of her brother Isaac in the Tom Tulliver of the same novel; and critics have traced a resemblance between her father and Caleb Garth in *Middlemarch*, and have identified her mother with the inimitable Mrs. Poyser in *Adam Bede*. These analogies must not be pushed too far, but that George Eliot's own personality is set forth in the character of Maggie Tulliver there can be no doubt. As a piece of unsparing self-revelation, a searching analysis of a child's moods and emotions, it can hardly be equaled. In Maggie she has drawn herself as an impetuous, proud, and highly sensitive child, with an instinct for passionate devotion to some one person—an instinct which throughout her life was vital in her. Like Maggie, too, she was not a precocious child, preferring play to study, and with difficulty learning to read. It must be admitted that at this time her stock of books was not altogether inspiring, among them being *Aesop's Fables*, *Joe Miller's Jest-Book*, and Defoe's *History of the Devil*; but she also read *The Pilgrim's Progress*, *Rasselas*, and *Waverley* and other novels of Scott. The local schools of Nuneaton supplied her early needs, and increased in her the strong religious and evangelical bent which characterized her youth, but the important formative years from 12 to 15 were passed at a school in Coventry. Her mother's death in 1836, devolving upon her much of the care of the farm, interrupted her studies temporarily. Yet she soon found means to gratify her awakened thirst for knowledge, studying among other subjects Italian, German, Greek, and Latin, though so assiduously and unsystematically that at the age of 19 she could describe her mind as "an assemblage of disjointed specimens of history, ancient and modern, scraps of poetry picked up from Shakespeare, Cowper, Wordsworth, and Milton, morsels of Addison and Bacon, Latin verbs, geometry, entomology, and chemistry."

When George Eliot was 21, her father's retirement from business and his removal to Coventry brought a momentous change into her life. Hitherto she had stifled in the intellectual isolation of dull, monotonous farm life. Henceforth her mental horizon was destined to grow steadily broader. At Coventry she met George Bray, the author of an *Enquiry Concerning the Origin of Christianity*, which profoundly affected her religious views. In the first enthusiasm of her new convictions she ceased to attend church—an attitude of open aggressiveness which almost led to a serious breach with her father. But friends effected a reconciliation, she agreed to attend services once more, and for the remainder of her life maintained a consistent tolerance towards the sincere beliefs of others, even when she regarded them as mere superstitions. It was through George Bray that she was led to undertake her first serious literary work, a translation, which a friend of Bray's had begun and discontinued, from the German of Strauss's *Life of Jesus*. The task absorbed her for two years, though it seems to have bored her sadly towards the end, and at times she revolted from her author's atti-

tude. In 1846, when her translation appeared, she declared herself "Strauss-sick"—it had made her ill to dissect the beautiful story of the crucifixion.

George Eliot's life as an author, from the appearance of the Strauss translation to the day of her death, may conveniently be divided into three periods—the first extending down to her union with Mr. Lewes in 1853; the second and third covering respectively her earlier and later novels, sharply divided by the production of *Romola* (1863). Her father's death in 1849 leaving her free, she made her first visit to the Continent, spending eight months in Geneva. A review of Mackay's *Progress of the Intellect*, which appeared in the *Westminster Review* (January, 1851) soon after her return, resulted in her appointment as assistant editor of that review, as reorganized by Mr. Chapman. Through the *Review* she came in contact with many of the chief literary lights of the period, with Froude and J. S. Mill, Theodore Parker and Harriet Martineau. But "her brightest spot is the deliciously calm new friendship that Herbert Spencer gives her," and it was through the latter that she met George Henry Lewes, with whom, in July, 1854, she formed a union which he and she regarded as matrimony.

To what extent an open disregard for accepted conventions may be excused by an honest belief in the integrity of one's own purpose can probably never be decided. It is certain that George Eliot felt deeply the censure of relatives and friends, yet at the same time she was firm in her conviction that her acts were justified. A legal marriage was impossible, since Lewes already had a wife living, from whom he was separated under circumstances that precluded the possibility of a divorce. But that both Miss Evans and Lewes regarded their union as possessed of all the solemn force of a lifelong tie there can be no doubt. Equally certain is it that whatever fame George Eliot achieved as a novelist, she owed in the first instance to the encouragement and unswerving faith of Lewes. Whether his influence in the working out of specific details of plot was always for the best may be questioned; but it is more than likely that without the stimulus of his belief in her powers her first novel would never have been written.

The Sad Fortunes of the Rev. Amos Barton, her first essay at fiction, appeared in *Blackwood's Magazine* in 1857 and was followed by *Mr. Gilfil's Love Story* and *Janet's Repentance*, afterward united in a single volume, *Scenes of Clerical Life* (1858). The volume evoked warm praise from many sources, notably from Thackeray, who thought the author was a man.

The personal side of George Eliot's life during the years following her discovery of her real talents may be summed up briefly. They were years of strenuous work, handicapped by a frail physique and brightened by pleasant summers in Germany, a few weeks in Florence in 1860 and 1861, gathering material for *Romola*, and a trip to Spain in 1867, in search of local color for *The Spanish Gypsy*. In November, 1878, the death of Mr. Lewes came as a crushing blow, but she found congenial occupation in planning and founding a studentship in his memory. Mr. John Walter Cross, who had long been on intimate terms with the Leweses, now became a constant visitor, and in the spring of 1880 George Eliot consented to marry him,

the marriage taking place on May 6. At this period she could write, "Deep down there is a river of sadness, but this must always be with those who have lived long—and I am able to enjoy my newly reopened life." She was not destined to enjoy it long. A serious illness in the autumn, followed by a relapse early in December, exhausted her vitality, and she died on the 22d of that month.

Which of her novels represents the culmination of George Eliot's powers is likely to remain a subject of controversy. Some critics will share with Mr. Oscar Browning the belief that her genius was of steady and uniform growth, reaching its greatest height in her last work, *Daniel Deronda* (1876). Others, like Sir Leslie Stephen, will continue to believe that nothing she produced subsequent to *Silas Marner* (1861) equals the volumes that preceded it. There will always be a select few who will look upon that remarkable *tour de force*, *Romola* (1863), as the turning point in her career; while the volume which has steadily enjoyed the widest popularity with the general reader is *Adam Bede* (1859). This last-mentioned story was suggested by an anecdote related to the author by an aunt, a Methodist preacher, who once passed a night in prayer with a girl condemned for child murder. The aunt became the Dinah Morris of the story and, at the suggestion of Lewes, was made the centre of interest from first to last—a change which more than one critic has censured. The lasting merit of this book, as of *The Mill on the Floss* (1860), which followed it, is less in the plot than in the marvelous alchemy which transforms the narrow, humdrum lives of dull-witted farming folk into vital pictures full of sympathetic appeal. *The Mill on the Floss* is sometimes pronounced an ill-proportioned piece of work, and the author herself admitted that her memories of childhood days lured her into unduly amplifying the earlier part. Yet it is the commonplace and wholly natural chatter of the Dodsons and Gleggs and Tullivers, the childish joys and sorrows of Maggie, her quarrels with Tom, her father's sympathy with his "little wench," that are remembered long after the later chapters of error and renunciation have grown dim. *Romola* was George Eliot's most ambitious work. It was an attempt to work out some deeply interesting ethical problems, not in the familiar atmosphere of her English midlands, but in the Florence of Savonarola and the Renaissance. The task demanded an amount of special research that was exhausting. She herself said of it that she began it as a young woman and finished it as an old one. It has sometimes been called the greatest historical novel ever written; and if profound erudition, a noble theme, and a fertile play of imagination are the first tests of an historical novel, this praise is justified. Yet it was not a commercial success when it appeared during 1862-63 in the *Cornhill Magazine*, which had paid £7000 for the serial rights; and critics most familiar with Italian life, such as Browning, Rossetti, and William Story, frankly said that they could not read it, because, in spite of the erudition, the book as a whole did not ring true. *Middlemarch* (1872), which represents a return to the author's earlier field, has had its share of champions. It has sometimes been defined as a great prose epic of English provincial life, a huge picture of the manners and customs

of social strata a degree or two higher up than the Dodsons and the Poyssers. Like real life, it is composite, an intricate fabric of many interwoven stories. Yet the principal actors—Dorothea and Casaubon, Rosamund and Lydgate—stand out distinct, familiar portraits in the permanent gallery of characters in English fiction. The fiercest controversy of all has been waged over *Daniel Deronda* (1876). It has been stigmatized as a tendency novel, the strongest proof of Lewes's pernicious influence. The characters have been pronounced severally and collectively unreal. Mordecai has been declared a bore, and his dream of restoring the Jewish nationality chimerical. Deronda himself is "an amiable monomaniac and prosy moralist." Yet other critics have seen in it "a work as far superior to *Adam Bede* as *Hamlet* is superior to *Much Ado About Nothing*," an effort to scale the loftiest heights and sound the lowest depths of human nature, and, conceding the impossibility of the task, have recognized the nobility of the partial failure.

George Eliot's serious claims to recognition as a poet rest almost wholly upon one long dramatic poem, *The Spanish Gypsy* (1868). The motive is a young girl's renunciation of happiness when, on the eve of marriage, she learns that her father is a gypsy, who is about to found a gypsy nation in Africa and requires her to sacrifice lover, country, and religion, in order to join him. The verse, however, is at best not of a high order, and the plot lacks common sense. In 1869 she published *Agatha*, a poem, and in 1876 *Jubal and other Poems*. Whatever popularity she has as a poet rests on the verses "O may I join the choir invisible." The first collected edition of her works was made in Edinburgh and London, 1878-80. An excellent recent edition in 25 vols. was published in Boston, Mass., in 1908. Consult: Haton, *George Eliot in Derbyshire* (London, 1876); *George Eliot's Life as Related in her Letters and Journals*, arranged and edited by her husband J. W. Cross (3 vols., ib., 1885); Parkinson, *Scenes from the George Eliot Country* (Leeds, 1888); James, *Partial Portraits* (London, 1888); Blinde, *George Eliot* (ib., 1883); Dowden, *Studies in Literature* (ib., 1878); Browning, *Life of George Eliot* (ib., 1892); Harrison, *The Choice of Books* (ib., 1896); Stephen, *George Eliot* (New York, 1902); Mottram, *The True Story of George Eliot in Relation to Adam Bede* (London, 1905); Brownell, *English Prose Masters* (New York, 1909); Deakin, *The Early Life of George Eliot* (Manchester, 1913).

ELIOT, or **ELIOTT**, GEORGE AUGUSTUS. See HEATHFIELD, GEORGE AUGUSTUS ELIOT, BARON.

ELIOT, SIR JOHN (1592-1632). An English patriot and statesman, born at Port Eliot, Cornwall, April 20, 1592. He spent three years at Exeter College, Oxford, where, however, he did not take a degree, and after studying law traveled on the Continent, where he became friendly with George Villiers, afterward Duke of Buckingham. At the age of 22 he entered Parliament and at 27 was made vice admiral of Devon, in which office he captured Nutt, a famous pirate, whose depredations were a constant infliction upon the commerce of the south-east coast. By bribery Nutt obtained his release and continued his depredations, while Eliot was imprisoned, on false charges, for four months in the Marshalsea. He received popular sym-

pathy and immediately upon his release, in 1624, was returned to Parliament, where, during the first three parliaments of Charles I, with Pym, Hampden, Selden, and Coke, he was the foremost leader in resisting the encroachments of the crown. He brought forward the idea of the separation of the different departments of government, which was later concretely expressed by Montesquieu. He spoke boldly against the venality of the ministry and the unwarranted foreign policy of his former friend Buckingham and urged Parliament to withhold supplies until an account was given of the money already voted. In 1625 he was instigator and leader of an attempt to impeach the Duke of Buckingham. He promulgated the theory of a responsible ministry. For comparing Buckingham to Sejanus he was imprisoned in the Tower in 1626, but the Commons compelled his release and exonerated him by special vote. He suffered another short imprisonment for petitioning the King against forced loans and later received sentence of outlawry. These persecutions only increased his popularity, and, though strenuously opposed by the court, he was again returned to Parliament in 1628. He took part in drawing up the Petition of Right and on the last day of that Parliament directed Holles and Valentine to hold the Speaker in the chair by force, while he read a protest against tonnage and poundage and other taxes and acts unauthorized by Parliament. Being summoned before the Council, with Holles, Selden, Valentine, and others, he refused to answer for his acts in Parliament except to Parliament itself and was confined in the Tower, with his fellow members, for more than two months, until popular indignation compelled the King to bring him to trial. The offenders were heavily fined and sentenced to be imprisoned during the King's pleasure, and not to be released until they had given security for good behavior, submitted to the King, and atoned for their offenses. The confinement of Eliot was greatly relaxed until they were all released, but Eliot could make no conscientious submission. The rigor of his imprisonment was increased, and his health suffered. His simple and manly petitions for temporary release were ignored, and he was allowed to sicken and die after two years' imprisonment, on Nov. 27, 1632. His death contributed largely to the downfall and execution of Charles. During the Commonwealth Eliot's sentence of conviction was reversed by act of Parliament. His writings include: *The Monarchy of Man* (1879); *An Apology for Socrates*, his own defense (1881); *Negotium Posterorum*, an account of the Parliament of 1625 (1881); *De Jure Majestatis* (1882); the *Letter-Book of Sir John Eliot* (1882). Consult John Forster, *Life of Sir John Eliot* (2d ed., London, 1871), and Gardiner, *History of England*, vols. v-vii (ib., 1893-95).

ELIOT, JOHN (1604-90). A clergyman and missionary of Roxbury, Mass., known as "the Apostle to the Indians." He was born at Widdowes, Hertfordshire, England, in 1604. He was educated at Jesus College, Cambridge. Influenced by Thomas Hooker, he became a non-conformist, and went to Boston in 1631. For a year he preached in the church of Mr. Wilson in Boston, and in 1632 became settled as "teacher" of the church in Roxbury. He remained there the rest of his life. He acquired

the language of the Pequot Indians from a young native taken prisoner in 1637. He first preached before the Indians without an interpreter at Nonantum, now Newton, about 5 miles west of Boston, on Oct. 28, 1646. This was the beginning of years of toil for the conversion of the Indians, during which Eliot traveled northward to the Merrimac River and into the southeastern part of Massachusetts and suffered many hardships of weather, travel, and opposition from the native sachems and priests. It was Eliot's policy to separate his converts from their old life and gather them into communities of "praying Indians." Such a settlement was made at Natick in 1651, and an Indian church organized there in 1660. He subsequently organized 16 such settlements. A "Society for the Propagation of the Gospel Among the Indians" was formed in London in 1649 and annually sent Eliot a sum of money to supplement the salary he received from the church at Roxbury. The outbreak of King Philip's War in 1675 interrupted the work and broke up the settlements of Christian Indians, but the latter rendered valuable service to the Colonists during the war. Eliot's *Catechism*, the first book printed in the Indian language, was published in 1653. His translation of the Bible was completed in December, 1658; the New Testament was published at Cambridge, Mass., in 1661, the Old Testament in 1663. It was the first Bible printed in America. A revision, in preparing which he had the assistance of the Rev. John Cotton, of Plymouth, was printed in 1680-85. His *Indian Grammar Begun* was printed at Cambridge in 1666. Of his *Indian Primer* (1669) the only complete copy known to exist is in the library of the University of Edinburgh. Other primers, catechisms, and translations of religious works for the Indians were prepared by Eliot. He assisted in preparing the famous "Bay Psalm-Book" (1640) and wrote several works in English. His *Christian Commonwealth, or the Civil Polity of the Rising Kingdom of Jesus Christ*, published in London in 1659, was criticized as containing seditious sentiments. After the Restoration the Governor and Council of Massachusetts required him to retract some of his statements. Eliot was a man of attractive personality, simple in life and manners, and kind in temper. He died at Roxbury, May 21, 1690. Consult: Francis, *John Eliot, the Apostle to the Indians*, in "Library of American Biography," vol. v (Boston, 1836); Winsor, *Memorial History of Boston*, vol. i (Boston, 1880-81); Walker, *Ten New England Leaders* (New York, 1901).

ELIOT, SAMUEL (1821-98). An American educator and historian. He was born in Boston, graduated at Harvard in 1839, and spent some years in study and travel in Europe. In 1856 he became professor of history and political science at Trinity College, Hartford, Conn., and from 1860 to 1864 was president of the same institution. From 1870 to 1873 he was a lecturer on history at Harvard, from 1873 to 1876 was head master of the Girls' High School in Boston, and from 1876 to 1880 was superintendent of the Boston public schools. As president of the American Social Science Association, he was active in the first organized movement for the reform of the civil service in 1869. He is the author of numerous historical works, among which are *The Ancient Romans* (1853) and *The Early Christians* (1853), forming the

first two parts of a projected *History of Liberty; A Manual of United States History between the Years 1792 and 1850* (1856, 1873); *Life and Times of Savonarola* (1856); *Poetry for Children* (1879); *Stories from the Arabian Nights* (1879); *Selections from American Authors* (1879).

ELIOT, SAMUEL ATKINS (1862-). An American Unitarian clergyman, son of Charles W. Eliot. He was born at Cambridge, Mass., graduated from Harvard in 1884 and held pastorates at Denver, Colo. (Unity Church, 1889-93), and Brooklyn, N. Y. (Church of the Saviour, 1893-98). From 1898 to 1900 he was secretary of the American Unitarian Association, and in 1900 he became its president. He wrote *A History of Cambridge, Massachusetts, 1630-1913* (1914) and contributed to the NEW INTERNATIONAL ENCYCLOPEDIA.

ELIOT, SIR THOMAS. See ELYOT.

ELIOTT, GEORGE AUGUSTUS. See HEATHFIELD, GEORGE AUGUSTUS ELIOT, BARON.

EL'IPANDUS. See ADOPTIAN CONTROVERSY.

EL'IPHAZ. One of the friends of Job. He is described in Job ii. 11 as a Temanite. The reputation for wisdom of the Edomites probably accounts for the choice of a native of the Edomitish district of Teman as the leader of the three friends. In the dialogues his speeches are characterized by a certain courtly dignity, kindness of judgment, and grace of style not so marked in the other interlocutors. His appeal to the authority of revelation and his general attitude are best reflected in the classical description of his vision in the night (Job. iv. 12-21). See Job.

ELIS (Lat., from Gk. Ἑλῖς, Elean *Fális*, *Valis*; connected perhaps with Lat. *vallis*, valley). One of the ancient divisions of the Peloponnesus, bounded north and northeast by Achæa, east by Arcadia, south by Messenia, and west by the Ionian Sea. It was originally divided into three districts—Cœle (or Hollow) Elis, Pisatis, and Triphylia. Of these the first named occupied the northern part and was by far the largest and most valuable, comprising the fertile plains watered by the Peneus and the Ladon, and producing excellent crops of wheat, cotton, and flax; while the pastures by the river banks reared cattle and horses of proverbial excellence. Pisatis, in the central portion, is drained by the Alpheus and is separated from Cœle Elis by Mount Pholœ, a spur of Erymanthus. The low grounds of this division possess great natural fertility. Its southern border was the Alpheus, at whose juncture with the Cladeos was situated the great sanctuary of Olympian Zeus. (See OLYMPIA.) South of the Alpheus was Triphylia, a continuation of the Arcadian hill country. Pisatis and Triphylia were subject districts, the ruling Eleans, or Epeians, dwelling on their fertile estates in the north. Though Elis had no natural strongholds and few fortified towns, it yet suffered little from war before the end of the fifth century B.C.—an advantage due in part to the sacred character of the country as the seat of the greatest of the national festivals and in part to its political situation, for the Elean oligarchy which controlled the cities early united the state to the Spartan League. During the Peloponnesian War, however, the Athenians harried the coasts, and from that time the fertile territory was frequently plundered. The inhabitants seem to have been unwarlike, and were

accused by the other Greeks of being addicted to lying, drunkenness, and licentiousness. Their prerogative of holding the Olympic games gave the Eleans a prestige which they continued to enjoy in greater or less degree till the games themselves were suppressed by the Emperor Theodosius in 394 A.D. Elis, now Kaloskopi, the capital of Elis, stood on the Peneus, and after its extension in 471 B.C., through the incorporation with it of various villages, became one of the important cities of Greece. Here were the three gymnasia in which all the competitors at the Olympic games were obliged to train for a month before the games at Olympia. Since 1899 Elis has formed a nomarchy of the Kingdom of Greece, the capital being Pyrgos. Consult Leake, *Travels in the Morea* (London, 1830), and Curtius, *Peloponnesos* (Gotha, 1852).

ELI'SHA (Heb., *Elisha*, God is deliverance). A prophet of Israel, who continued the movement of Elijah against the Baal cult. The story of his career is told in 2 Kings ii, ix, xiii, as follows: He was the son of Shaphat and lived at Abel-meholah, where until his call he was a farmer (1 Kings xix. 19). While at Horeb, Elijah is told to appoint Elisha his successor; this he does by throwing his mantle over him, whereupon Elisha sacrifices the oxen with which he was plowing, and follows Elijah. During the life of his master nothing is heard of Elisha until immediately before Elijah's death. Elisha follows him from Bethlehem to Jericho and then across the Jordan, which Elijah divides with his mantle, and as Elisha is taken up he receives the mantle of his master (2 Kings ii. 13). Elisha also divides the Jordan and comes to Jericho, where he heals the poisonous waters (2 Kings ii. 19-22). On the road to Bethlehem he is met by children who laugh at him for his bald head. He curses them, and 40 of their number are devoured by two she bears (2 Kings ii. 23-25). He severely rebukes Jehoram and refuses to speak to him, but prophesies for the sake of Jehoshaphat (2 Kings iii). A wife of one of the sons of the prophets coming to Elisha for aid, he performs the miracle of the oil (2 Kings iv. 1-7) and restores to life the son of another woman who has befriended him (2 Kings iv. 8-37). Another miracle like that performed at Jericho was the removing of the poison from the food prepared by the sons of the prophets (2 Kings iv. 38-41). Still another miracle is the making 20 loaves of bread serve 100 men (2 Kings iv. 42-44). He cures Naaman of Syria of his leprosy and refuses to take any return for it and curses his servant Gehazi for having taken a present (2 Kings v). He strikes the Syrian army with blindness, but sends them away in peace after he has brought them to Samaria (2 Kings vi. 8-23). When he sees Hazael, he knows at once the suffering that will be brought on Israel, but still tells Hazael that he will be king (2 Kings viii. 7-15). To fulfill the prophecy of Elijah, Elisha sends a prophet to anoint Jehu, who promptly kills the family of Ahab and takes the throne (2 Kings ix). Before his death Elisha is visited by Joash and predicts three victories against the Syrians (2 Kings xiii. 14-19). Even after his death Elisha performs miracles; a body thrown upon his bones revives and stands up (2 Kings xiii. 20-21).

The character of the Elisha stories, it will be seen, is very much the same as that of those told of Elijah. Both perform miracles, restoring

dead persons to life, striking the living with disease, predicting victories or disasters, and the like. While not so rugged as Elijah, he surpasses the latter in the political influence that he exercises. The narrative clearly indicates a progress towards the recognition of Yahwe to the exclusion of the Baal cults, so that Elisha's path is considerably smoother, owing to the antecedent activity of Elijah. Consult Dodds, *Elisha the Man of God* (1904), and Erbt, *Elisha, Jona* (1907).

ELIS'SA. See DIDO.

ELIX'IR (Fr. *élixir*, OF., Sp. *elixir*, from Ar. al *iksir*, the philosopher's stone, probably from Gk. *ἐξῆρος*, *wēros*, dry, less plausibly from Ar. *kasara*, to break). A term in pharmacy, applied to various preparations, consisting mostly of solutions of aromatic and bitter vegetable substances in spirits of wine. The term "tincture" is now more common. *Elixir of vitriol*, or aromatic sulphuric acid, is prepared from 1½ fluid ounces of sulphuric acid, 10 fluid ounces of rectified spirit, ½ ounce cinnamon in powder, 1 ounce ginger in powder. While elixirs are made in great variety, but three are official in the United States Pharmacopœia: Elixir Aromaticum, Elixir Adjvans (both flavorings), and Elixir of Quinine, Iron, and Strychnine. See CHEMISTRY.

ELIZABETGRAD, yě-lě'sà-bět-grad'. See YELIZAVETGRAD.

ELIZ'ABETH. A city and the county seat of Union Co., N. J., 12 miles by rail southwest of New York City, and 4 miles south by west of Newark, on the Elizabeth River, Staten Island Sound, and on the Central of New Jersey, the Pennsylvania, and the Lehigh Valley railroads (Map: New Jersey, D 2). Elizabeth has steamboat connection with New York, and its shipping facilities by land and water are extensive. Its port is accessible to vessels drawing 25 feet at low water and it receives large quantities of coal and iron brought by rail from the Pennsylvania mines for reshipment. The principal industrial establishments are sewing-machine works, oil refineries, foundries, chemical works, leather and rubber works, shipbuilding plants, and manufactories of wire and cable, tools, electro motors, castings, machinery, and bronze powder. The value of the combined output of the industries in 1909 was \$29,147,000. Elizabeth is the suburban home of many New Yorkers, is laid out with broad and well-paved streets, and has several parks and many fine residences. It contains also a public library, three hospitals, an orphan asylum, and a splendid high-school building.

The city has several places of historical interest. It was settled in 1664 by a company from Long Island, and on May 26, 1668, the first General Assembly of New Jersey convened here. Elizabeth was the capital of the Colony from 1755 to 1757 and suffered greatly during the Revolution. It was chartered as the "Borough of Elizabeth" in 1789, incorporated as a town in 1796, and received a city charter in 1855. The city's receipts in 1913 amounted to \$2,211,200; its expenditures were \$2,127,900, the chief items being: police, \$106,000; fire, \$87,000; education, \$280,000. The College of New Jersey, founded here in 1746, later developed into Princeton University. Alexander Hamilton and Aaron Burr spent part of their early lives at Elizabeth. There are many fine types of architecture of the Revolutionary period still standing. Pop., 1890, 37,764; 1900, 52,130; 1910, 73,409; 1914

(U. S. est.), 82,411. Consult Hetfield, *History of Elizabeth* (New York, 1868).

ELIZABETH (1533-1603). Queen of England. She was the daughter of Henry VIII and the unfortunate Anne Boleyn and was born Sept. 6, 1533. While she was yet in her third year, her mother was beheaded. After the mother's execution Elizabeth was sent to the country, where the greater part of her early youth was spent. When Catharine Parr became Queen, Elizabeth, who was a favorite with her, was more often seen at court; but for some unknown cause she incurred her father's displeasure and was again sent to the country. Her father died when she was 13 years old. During the reign of her brother, Edward VI, her life passed quietly and peacefully. She was then remarkable for great demureness, so that Edward used to speak of her as his "sweet sister Temperance." Her Protestantism, and the court which was paid to her by the Protestant nobility, caused uneasiness to Edward's successor, Mary, and her Council. At her sister's command she conformed to the Roman Catholic faith, but the insincerity of the conversion imposed upon no one. On the pretext of having been concerned in Wyatt's rebellion, she was sent in 1554 to the Tower. The warrant for her execution was at one time prepared, but her popularity saved her, as her sister's advisers feared an uprising if Elizabeth were put to death. Nevertheless for some time longer she was kept a prisoner at Woodstock. During the remainder of Mary's reign Elizabeth, though occasionally at court, resided chiefly at her residence at Hatfield House in Hertfordshire.

When Mary died, Nov. 17, 1558, Elizabeth was 25 years of age. Her accession was welcomed alike by Catholics and by Protestants. She then began, amid dangers and difficulties, a reign which, contrary to the expectation of all, was of unexampled length and prosperity. It would be wrong not to attribute to her influence some effect in producing the great changes which during the next 44 years took place in England; but so far as these changes were not produced in the natural course of the development of the nation's power, and so far as they bear the mark of an individual mind, they bear much more the impress of the bold yet cautious judgment and clear intellect of her great minister, Cecil, than of Elizabeth. The essentially Protestant character of her policy was shown at the very beginning of her reign, and in consequence of this a Protestant majority was returned to her first Parliament. In 1559 a new Act of Supremacy was passed. In 1560 Elizabeth concluded a treaty of alliance at Berwick with the Scottish Reformers, who were joined by an English force. The Thirty-nine Articles of the Church of England were published in 1563.

The policy of Elizabeth's ministers, on the whole, was one of peace and economy. No war was undertaken in her reign for the sake of territorial conquest. To strengthen her own throne, Elizabeth assisted the Protestants in Scotland, in France, and in the Low Countries; but she had few open wars. To maintain her own security, and to prevent foreign interference in English matters, was the mainspring of her foreign policy; and she lost no opportunity of weakening and finding occupation abroad for any foreign power that unduly threatened her authority. Her diplomacy was tortuous and swayed by innumerable changes of mind, but she usually

attained her ends. Her parsimony was well known and sometimes disastrous. Had she given ample succor to the Dutch, as the English nation wished, the result of the war would have been much more advantageous to England. The inadequate provisions and ammunition of the English fleet would likely have led to bad results had the Spanish Armada been placed in more competent hands. However, her parsimony was necessary while the nation was poor. The one great blunder of Elizabeth's policy was the treatment of Mary, Queen of Scots, who, after her defeat by the Regent Murray at Langside in 1568, had sought refuge in England, only to become a captive in the hands of the English Queen. Daring neither to execute her prisoner, as several of the ministers advised, nor to release her, in which case she would probably have gone to Spain or France and by a foreign marriage have forfeited the sympathies of the Scottish and English Catholics, Elizabeth retained her a prisoner, and thus for years gave cause for conspiracy after conspiracy among the English Catholics. For a rebellion incited to set Mary free, the richest and most popular of the English nobles, Norfolk, was executed in 1572. The plots then took on a graver aspect. The assassination of Elizabeth and the placing of Mary on her throne became their object. On the discovery of Babington's conspiracy for this purpose, the popular cry for Mary's death was irresistible, and was joined in by Cecil, Walpole, and others of Elizabeth's ministers. With reluctance and hesitation Elizabeth consented; and Mary, after long years of confinement, was condemned and executed in 1587.

This led to new evils. The participation of the Catholic party in the plots was punished by persecution. Many suffered under an Act passed in 1585 which made it treason for a Catholic priest to be in the country and felony to harbor one. These measures were the ultimate means of bringing upon England a most menacing foreign attack. Philip of Spain had long meditated vengeance against England for her aid to the Dutch Protestants against Alva and for her freebooting attacks on Spanish commerce. To restore the Catholic faith and to avenge the death of a Catholic queen furnished reasons which were more than pretexts to Philip, who was filled with the desire to promote the Catholic faith. In 1588, after years of preparation, the "Invincible Armada" (see ARMADA) sailed from the Tagus, manned by 8000 sailors and carrying nearly 20,000 soldiers. To aid them a land army of 100,000 men was to be transported from the Netherlands under the Duke of Parma. The news roused all England, and every man who could carry arms from 18 years of age to 60 was enrolled in the forces. The Queen herself rode at Tilbury, energetically encouraging the army. The English fleet, under Howard and Drake gathered on the southern coast, awaited the attack. Superior skill and courage gained the victory for the English; and what they had begun the force of the elements completed. The splendid armada was broken and destroyed before it could join the land army, and the great Spanish expedition came to naught.

The close of Elizabeth's reign was disturbed by a formidable revolt in Ireland under the Earl of Tyrone. The Queen's favorite, Essex, who was sent against him, showed himself utterly incompetent; but the Irish leader succumbed at last to the arms of Lord Mountjoy.

QUEEN ELIZABETH
FROM AN ENGRAVING BY T. A. DEAN, AFTER A PAINTING BY FEDERIGO ZUCCARO

Elizabeth died March 24, 1603, at the age of nearly 70 years. Always parading her wish to live an unmarried life, Elizabeth coquetted with suitor after suitor. She was scarcely more than a child when her flirtations with the handsome Lord Admiral Seymour, the brother of the Protector Somerset, had passed the bounds of decorum. In Mary's reign Elizabeth was flattered by the attentions of her kinsman, the Earl of Courtenay, and she declined the hand of Philibert of Savoy, pressed on her by her sister's Council. When Queen, she refused with some hesitation the offer of Philip II, who was desirous of perpetuating his influence over England, and she began a connection with the Earl of Leicester which seriously compromised her character. If we credit those sources of information which are found in the dispatches of the Bishop of Aquila, Ambassador of Philip II in London, preserved in the archives of Simancas, not only was the moral character of Elizabeth sullied, but even the quality for which she has ever been most honored, her English patriotism, was mere affectation. These dispatches represent her as proposing to Spain to become a Catholic and to restore the Spanish ascendancy in England if Philip would support her on the throne as the wife of Leicester. That there is some basis of truth in this revelation can scarcely be denied; but, aside from the fact that the Bishop exaggerated, Elizabeth, who was often mendacious, was probably deceiving him. If she really intended to marry Leicester, she was prevented by the advice of her ministers, especially of Cecil. Among less distinguished suitors the Archduke Charles of Vienna and Prince Eric of Sweden urged their suit in vain. Petitions from Parliament to the Queen to marry produced only dignified replies that she would attend to the matter when the time came. Catharine de' Medici, Queen mother of France, intrigued to marry her to one of her sons, Henry of Anjou, with whom she carried on an absurdly ardent courtship for a lady 18 years his senior. Her last favorite was the Earl of Essex, unworthy but good-looking, whom she executed for treason. Nevertheless she never let affairs of state be guided by these favorites, but relied on the wisdom of her ministers, chief of whom were William Cecil, Lord Burghley, and Sir Francis Walsingham, her Secretary of State.

Elizabeth's position gave notoriety to the unamiable and ridiculous features of her character. She was vain in dress, rather mannish in demeanor, and lacked fine feeling; but in her reign the reckless waste of human life which marked the reigns of her predecessors was unknown. The cruel persecutions of the Catholic seminary priests are in line with the spirit of the times and are not to be attributed to Elizabeth personally. By her attendants she was feared more than loved. The one quality which never failed her was personal courage; and when she chose, her demeanor was stately and royal. Religion was with her, as with a great proportion of the nation at that time, a matter more of policy and convenience than of feeling or principle. She preferred Protestantism because of early associations and because it gave her the headship of the church, freed her from foreign interference, and was more acceptable to her ministers and to the nation. The above estimate of Queen Elizabeth is based upon the famous chapter in Green's *History of the English People* describing the character of the Queen.

In the long reign of Elizabeth the true greatness of England began. Freed from the possession of those French provinces which rather harassed than enriched, with little domestic commotion, with no foreign wars, with an almost complete immunity from religious persecution, the nation turned to the arts of peace. An unequalled literature arose. The age that produced Spenser, Shakespeare, and Bacon could not be other than famous. Under Frobisher and Drake maritime adventure began, and the foundations of the British navy were laid. Commerce, from being a small matter in the hands of a few foreign merchants, assumed great proportions. The Royal Exchange of London was opened in Elizabeth's time, and in the charter granted to that company of merchants which afterward took the name of the East India Company may be seen one of the small beginnings of the vast colonial British Empire. The social condition of the people also greatly improved in her reign. The crowds of vagabonds which the monastic institutions had fostered, and which had been increased by the eviction of tenants on monastery lands, died out or were absorbed in industrial employments. The last traces of bondage disappeared. Simultaneously with the growth of greater comfort and intelligence in the people, Parliament began to assert with greater vigor its constitutional rights. The right of the Commons to free speech and to initiate all money bills was steadily asserted, and the right of the crown to grant monopolies or to issue proclamations having the force of law vigorously assailed, and the reign of Elizabeth may be said to mark the transition from mediæval to modern England.

There is abundant original material for a biography of Elizabeth. Chief among the sources is the *Calendar of State Papers* of her reign, especially the *Spanish Series*, ed. by M. A. S. Hume (London, 1892-99). The *Manuscripts at Hatfield House* (Royal Historical Manuscripts Commission, 1888-95) are most useful; as are the *Burghley Papers*, ed. by S. Hayes (London, 1740) and W. Murdin (ib., 1759). *State Papers*, ed. by A. Collins (ib., 1746), *Miscellaneous State Papers*, ed. by Earl of Hardwicke (ib., 1778), and others. Several of the *Camden Society Publications* are also very useful: *Letters of Elizabeth and James VI*, ed. by J. Bruce (1849); *Machyn's Diary*, ed. by J. G. Nichols (1848); and *Walsingham's Chronicle*, Camden Miscellany (1847-75). The most important contemporary account of the reign is that by W. Camden, *History of Queen Elizabeth* (1622), and a continuation by Godwin in Kennet's *Complete History of England* (London, 1740). Consult Strype, *Annals of the Reformation* (new ed., Oxford, 1824), a standard for ecclesiastical matters, and D'Ewes, *Journals of All the Parliaments of the Reign of Queen Elizabeth*, ed. by P. Bowes (London, 1682), which is indispensable. Among modern authorities the most detailed account of the reign is to be found in Froude, *History of England*, vols. vii-xii (New York, 1870); Wright, *Queen Elizabeth and her Times* (London, 1838), based on private letters of the reign; Creighton, *Queen Elizabeth* (ib., 1899), a good popular life, as is E. S. Beesley, *Queen Elizabeth* (ib., 1902); but perhaps the best is A. Jessup's excellent article in the *Dictionary of National Biography*. Strickland's *Lives of the Queens of England* (New York, 1867) contains a life of Elizabeth which is useful as a personal memoir, and Wiesener's *La*

jeunesse d'Elizabeth d'Angleterre, 1533-58 (Paris, 1878, Eng. trans. by C. M. Young, 1879), deals with Elizabeth's youth. For the constitutional development of Elizabeth's reign consult: the works of Hallam, vol. i, chap. v; Taylor, vol. ii, bk. iv, chap. v; Gneist, vol. ii, chaps. xxx-xxxvi, passim (full titles cited under GREAT BRITAIN). For economic development, Traill, *Social England*, vol. iii, chaps. xi, xii, and Cunningham, *English Industry*, vol. ii, bk. vi. The last years of the reign are treated exhaustively in E. P. Cheyney, *A History of England from the Defeat of the Armada to the Death of Elizabeth*, vol. i (London, 1914). The Elizabethan religious settlement is the subject of a brilliant contribution by F. W. Maitland to the *Cambridge Modern History* (vol. ii, chap. xvi).

ELIZABETH (1545-68). A queen of Spain, daughter of Henry II of France and of Catharine de Medici. She was born at Fontainebleau, and although from infancy pledged in marriage to Don Carlos, the heir presumptive to the Spanish throne, afterward espoused the father of the latter, Philip II. Owing to the cruelty of Philip and the early death of the parties concerned, the story of an attachment between Elizabeth and Don Carlos gradually spread among the people. It has been perpetuated in several stories and romances, and notably in Schiller's celebrated drama *Don Carlos*. There seems to be nothing in the known facts of the history of the period to substantiate the legend, and it is well known that Elizabeth, like all the rest of his wives, fairly adored Philip II.

ELIZABETH (1618-80). A Princess Palatine. She was born at Heidelberg, the eldest daughter of the unfortunate Elector Palatine Frederick V, for a brief period King of Bohemia, and of Elizabeth Stuart, daughter of James I of England. She was brought up at The Hague and was a pupil of William Penn in religion and of Descartes, who dedicated to her his famous *Principia Philosophiæ*, and who found in her the rare union of metaphysical and mathematical capacity. She was nicknamed "la Grecque." She refused an offer of marriage from the King of Poland and in 1667 became Abbess of Herford, thereafter gathering about her mystics of various kinds.

ELIZABETH, AMÉLIE EUGÉNIE, à-l'è-zà-bèt à-mä'l'è-à oi-gä'nè-à (1837-98). Empress-queen of Austria-Hungary, wife of Francis Joseph, ruler of the Austro-Hungarian monarchy. She was a daughter of Duke Maximilian Joseph of Bavaria. She was a remarkably beautiful and intelligent woman and spoke a number of languages. A daring horsewoman and fond of sports, she spent much of her time on her estates or in travel. While on a visit to Geneva, she was stabbed (Sept. 10, 1898) by Luccheni, an Italian anarchist, and died a few minutes afterward. Consult: De Burgh, *Elizabeth, Empress of Austria* (London, 1898); Friedmann, *Kaiserin Elisabeth* (Berlin, 1898); and the anonymous and gossipy *Martyrdom of an Empress* (London, 1899).

ELIZABETH, CAPE. See CAPE ELIZABETH.

ELIZABETH, PAULINE ELISABETH OTILIE LOUISE (1843-). Queen of Rumania; known as a poet and novelist, under the name of Carmen Sylva. She was born at Neuwied, Germany, a princess of Wied, but after her marriage with Prince Charles of Rumania, in 1869, she identified herself with the Rumanian people. In the Russo-Turkish War of 1877-78 she was

untiring in her care of the wounded. The customs and the folklore of the Rumanians are the subjects of her poetry, which is full of homely beauty in its expression of nature and life. She was elected in 1914 an honorary fellow of the Royal Society of Literature of the United Kingdom. Among her numerous books in verse and prose are: *Leidens Erdengang* (1882; 5th ed., 1899, trans. into English by Helen Zimmern as *Pilgrim Sorrows*); *Jehovah* (1882); *Pensées d'une reine* (1882); *Handwerkerlieder* (1891); *In der Lunca* (1904); the essays, *Geflüsterte Worte* (1903; 1906). For her biography, consult Diederich (Leipzig, 1898) and Roosevelt (London, 1891).

ELIZABETH, PHILIPPINE MARIE HÉLÈNE, called MADAME ELIZABETH (1764-94). A princess of France, sister of Louis XVI, born at Versailles. She was of a noble and charitable disposition and, although she had never participated in politics, was prompted by her sense of duty and her affection for her family to leave their countryseat at the outbreak of the Revolution in order to be at the side of her brother, the King of France. Accused of carrying on a correspondence with the royal princes and of providing them with money, she was sentenced by the Revolutionary Tribunal, May 9, 1794, and executed the following day. Consult Mrs. Maxwell-Scott, *Madame Elizabeth of France* (1908).

ELIZABETH, SAINT (1207-31). The daughter of Andrew II, King of Hungary, born at Pressburg. At the age of four she was affianced to Louis, eldest son of the Landgrave of the Thuringia, and was taken to the Wartburg to be educated under the eyes of the parents of her future husband. She early displayed a passion for asceticism as it was conceived in those days. She despised pomp, avarice, and ambition, cultivated humility, and exhibited the most self-denying benevolence. Her conduct even as a girl astonished the Thuringian court; but such was the grace and sweetness of her disposition and the excellence of her beauty that Louis, though her affections seemed to be given wholly to God, still wished to marry her. They were united when Elizabeth was only 14. On the death of her husband in 1227 she was deprived of the regency by the brothers of her deceased husband and driven out, together with her four children, on the plea that she wasted the treasures of her state by her charities. Later she was offered the regency, which she refused. She spent her last days as a member of the third order of St. Francis, subjecting herself to mortifications which shortened her life. She was canonized in 1235. Charles Kingsley's dramatic poem, *The Saint's Tragedy*, is founded on the story of Elizabeth's life. Consult Montalembert, *Life of St. Elizabeth*, trans. by F. D. Hoyt (London and New York, 1904), and Wenck, *Die Heilige Elisabeth* (Tübingen, 1908).

ELIZABETHAN ARCHITECTURE. A term applied to the mixed style which sprang up in England on the decline of Gothic architecture. By some it is confused with the Tudor style (q.v.), out of which it sprang. The Elizabethan is chiefly exemplified by mansions erected for the nobility in the reigns of Elizabeth and James I, and originated in the new conditions of domestic life and manners which marked the sixteenth and early seventeenth centuries. The gradual change of style in manor houses and palaces reveals the first introduction of

classic details, influenced, no doubt, by Holbein, who was patronized by Henry VIII and furnished several designs in this manner, and by the relations of England with Protestant Holland and Germany, from which, rather than from Italy, the new forms were derived. John of Padua succeeded Holbein and built in the mixed style a palace for the Protector Somerset (for which purpose the cloisters of St. Paul's were taken down), and the mansion of Longleat for his secretary, Sir John Thynne. The curved broken gables, pilasters broken by quoins and bands, and the tormented details are characteristic. So are the vast dimensions of the apartments, the enormous square windows, the carved wooden staircases, the multiplication of fireplaces and chimneys, the picturesque gables, octagonal turrets, and projecting bay windows. The ornament, especially the "strapwork," lacks delicacy; but the plaster ceilings are often paneled with great elegance. Carved wooden screens divide some of the great halls, and open timber ceilings are still used. The classic orders, coupled and superposed but of incorrect proportions, are common as doorway decorations, and gables (see GABLE) are a frequent substitute for pilasters. The following examples of mansions of the seventeenth century may be still seen near London: Holland House, Campden House in Surrey, Bramshill in Kent, Sir T. Wilson's at Charlton, the Marquis of Salisbury's at Hatfield, and Knowle, the property of the Lord Sackville. Others are Burton Agnes, Audley End, Aston, Burghley, Kirby Hall, Montacute, Mogus Park, and Blickling. The most eminent architects of those times were John Thorpe, Gerard Christmas, Rodolph Symonds, and Thomas Holt. Consult: Richardson, *Architectural Remains of the Reigns of Elizabeth and James I* (London, 1840); Blomfield, *History of Renaissance Architecture in England* (ib., 1897); Gotch and Brown, *Architecture of the Renaissance in England* (ib., 1894).

ELIZABETH CHARLOTTE (1652-1721). A duchess of Orléans. She was born at Heidelberg and was a daughter of the Elector Palatine, Charles Louis, and a Hessian princess. Although thoroughly German in temperament and tastes, she was for political reasons married to Duke Philip of Orléans, brother to Louis XIV, in 1671. The fearful devastation of the Palatinate by Louis XIV (1689), which filled all Europe with horror, was the result of claims to territory which the "Grand Monarque" made on the strength of this marriage. The extensive correspondence of Elizabeth with her family (7 vols., 2d ed., published in 1867-82) and with

Leibnitz throws very interesting side lights upon the history of the period.

ELIZABETH CITY. A city, port of entry, and the county seat of Pasquotank Co., N. C., 53 miles south of Norfolk, Va., on the Norfolk and Southern and the Virginia and Carolina Coast railroads, and on the Pasquotank River (Map: North Carolina, F 1). Elizabeth City contains a State normal school and United States customhouse. It has a good harbor, large trucking interests, and a considerable trade in cotton, lumber, and fish, oyster cultivation being an important industry. There are saw and planing

BLICKLING HALL.

mills, shingle factories, cotton and hosiery mills, cotton gins, flour and grist mills, ironworks, machine shops, a shipbuilding yard, and manufacturing of bricks, carriages and wagons, barrels and baskets, boxes, etc. The government is vested in a mayor, who holds office for two years, a board of aldermen, and a board of control. Pop., 1900, 6348; 1910, 8412; 1914 (U. S. est.), 9292.

ELIZABETH FARNESE, fär-nā'zā. See FARNESE.

ELIZABETH ISLANDS. A group of 16 small islands belonging to Massachusetts, lying southwest of Barnstable County and between Buzzards Bay and Vineyard Sound (Map: Massachusetts, F 5). In 1864 they were in-

incorporated as Gosnold Township of Dukes County. They cover an area of 14 square miles. The islands, of which Naushon and Nashawena are the two largest, have a fine climate and scenery and afford excellent fishing. They are popular summer resorts. Permanent pop., 1910, 152. On Cuttyhunk Island the foundations of the first English colony of New England were laid in 1602 by Bartholomew Gosnold, only to be abandoned the same year.

ELIZABETH PETROVNA (1709-62). Empress of Russia from 1741 to 1762. She was the daughter of Peter the Great and Catharine I and was born Dec. 18, 1709. On the death of her nephew Peter II, in 1730, she suffered Anna, Duchess of Courland, daughter of Ivan V, to ascend the throne. (See ANNA IVANOVNA.) Anna died in 1740, and Ivan, the son of her niece Anna Karlovna (q.v.), an infant of two months, was declared Emperor, and his mother made Regent during his minority. Shortly after this a plot was formed to place Elizabeth upon the throne; the two principal agents in it were Lestocq, a surgeon, and the Marquis de la Chetardie, the French Ambassador. The officers of the army were won over, and on the night of Dec. 5, 1741, the Regent and her husband were taken into custody, and the child Ivan was conveyed to Schlüsselburg. By eight o'clock in the morning the revolution was accomplished. La Chetardie was handsomely rewarded; and Lestocq was created first physician to the Empress, president of the Academy of Medicine, and Privy Councillor. Elizabeth was energetic, full of energy, knowledge, and a love of business, and allowed herself to be guided by favorites; for this reason corruption prevailed at her court. In order to strengthen her position she took pains to win over her nephew the young Prince Peter, the son of her sister the Duchess of Holstein-Gottorp. She summoned him to St. Petersburg in the year 1742 and proclaimed him her successor. She took part in the War of the Austrian Succession and dispatched a large army to the assistance of Maria Theresa, thereby securing the conclusion of the Peace of Aix-la-Chapelle in 1748. At the commencement of the Seven Years' War she allied herself with Austria and France against Prussia. Her troops won the battles of Gross-Jägerndorf and Kunersdorf and raided Berlin, but without any decisive result. Elizabeth died Jan. 5, 1762, before the expiration of the war. She founded the University of Moscow and the Academy of Arts at St. Petersburg. Consult: Bain, *The Daughter of Peter the Great* (London, 1899); Vandal, *Louis XV et Elisabeth de Russie* (Paris, 1862); Weidmayer, *Règne d'Elisabeth Petrovna* (St. Petersburg, 1849).

ELIZABETH STUART (1596-1662). A queen of Bohemia. She was the eldest daughter of James VI of Scotland, afterward James I of England, and was born at Falkland Castle in Fifeshire, Aug. 19, 1596. After 1608 she resided at court and took part in the life of the gayest circles. In 1613 she married Frederick V, Elector Palatine of the Rhine, who in 1619 was summoned by the Protestants of Bohemia to be their King. Frederick's forces were defeated by the Catholic army at Prague in 1620, and he was driven from his throne. The Palatinate was invaded in 1622 and taken from him, and the Diet of Ratisbon declared the electoral dignity forfeited. With her husband and children, Elizabeth sought refuge in Holland. Frederick died in 1632, but it was not until 1648 that the

Palatinate was restored to Elizabeth's second son, Charles Louis, the eldest, Frederick Henry, having died in 1629. She returned to England in 1661, but mingled very little in society, and died Feb. 13, 1662, at the house of Lord Craven in Drury Lane, London. Of her other children, the most celebrated were Prince Rupert (q.v.) and Prince Maurice. Her youngest daughter, Sophia, married Ernest Augustus of Brunswick-Lüneburg, later Elector of Hanover, and became the ancestress of the present reigning house of Great Britain. The best biography of Elizabeth is that by Mrs. Everett Green, in *Lives of the Princesses of England* (London, 1854), which has superseded Miss Benger's *Memoirs of Elizabeth Stuart, Queen of Bohemia* (ib., 1824). A good short account is given in R. S. Rait, *Five Stuart Princesses* (New York, 1908).

ELIZABETHTOWN. A city and the county seat of Hardin Co., Ky., 42 miles south of Louisville, on the Louisville and Nashville and the Illinois Central railroads (Map: Kentucky, E 4). It has flouring mills, stave and overall factories, and dairying interests, and carries on a considerable trade in live stock, grain, flour, fruit, brick, and tobacco. It has municipal water works. Pop., 1900, 1861; 1910, 1970.

ELIZABETHTOWN. A borough in Lancaster Co., Pa., 17 miles southeast of Harrisburg, on the Pennsylvania Railroad (Map: Pennsylvania, H 7). It contains a Masonic home and Elizabethtown College. There are manufactures of shoes, agricultural implements, shirts, wagons, and cigars, and large tobacco warehouses. Pop., 1900, 1473; 1910, 2587.

ELIZABETPOL, yě-lě'sá-bět-pól. See YE-LIZAVETPOL.

ELK (AS. *elch*, Icel. *elgr*, OHG. *elaho*, elk, Ger. *Elch*, whence probably Lat. *alces*, Gk. *ἀλκη, alkē, elk*). 1. The greatest forest deer (*Alces malchis*, or *alces*) of the northern regions of Europe and Asia and the largest existing representative of the family. A closely related species (*Alces americanus*) is known in America as the moose, under which name its characteristics are described. In the Old World the elk formerly ranged throughout all the forested region north of the mountains from England to eastern Siberia, and it still occurs rarely in Scandinavia, eastern Prussia, Lithuania, and parts of Russia, while it remains fairly numerous in western Siberia; everywhere in Europe it is protected by laws, and in most cases is preserved on royal estates, where a hunt is organized at intervals of several years. It may easily be tamed and has at various times been put to service, having at one time been trained to draw sledges in the government's courier service in Sweden. See Moose.

2. The American "elk," unfortunately so named by the early colonists of the United States, has no resemblance to the European broad-horned deer, properly so called (see above), but rather resembles the red deer. (See DEER.) It is described under its suitable Indian name. See WAPITI.

3. The Irish "elk" (*Cervus*, or *Megaceros, giganteus*) is another misnamed deer, which became extinct apparently soon after the advent of man in Europe. It remains are found not only in the bogs of Ireland, but in caves and superficial deposits of England, Scotland, and the middle parts of the Continent. It was closely allied to the fallow deer, but of much

greater size, standing 6 feet in height, with unusually strong bones about the head and neck, suitable for carrying the enormous antlers which characterized it. These were broadly palmated and were so widespreading as to measure, in some known instances, almost 11 feet from tip to tip. Its bones have been found associated with the evidences of man's presence, showing that it survived his arrival and that its extermination was probably completed by human agency. Another extinct species (*Cervus rufi*), of central Europe, takes a place between this species and the fallow deer. For a description of the different kinds, see the article DEER, and for illustrations see its accompanying Plate of DEER OF NORTH AMERICA.

EL-KATIF, el-kā-tēf'. A fortified seacoast town of El-Hasa, Arabia, situated on the west shore of the Persian Gulf, a short distance northwest of Bahrein Island (Map: Turkey in Asia and Arabia, F 5). It has an old Portuguese citadel. Pop., about 10,000.

ELK CITY. A city in Beckham Co., Okla., 20 miles southeast of Cheyenne, on the Chicago, Rock Island, and Pacific and the Wichita Falls and Northwestern railroads (Map: Oklahoma, B 3). It has broom factories, a flouring mill, a cotton-oil mill, a cotton compress, an ice plant, and agricultural and other interests. The water works are owned by the city. Pop., 1900, 2,195; 1910, 3,165.

ELKESAITES, ēl-kēs'ā-its, or **ELCESAITES** (named after their reputed founder Ἐλκασαί, *Elchasai*, 'Elkesai, *Elkesai*, or Ἠλξάτ, *Elxat*; they themselves derived their name from Heb. *heil kesai*, hidden might). An Ebionite (q.v.) sect of the second century which laid great stress upon baptism. They held as the highest authority a work known as the Book of Elkesai, which was known to Origen, Hippolytus, and Epiphanius. The last reports that it was believed to have been revealed by an angel who was the Son of God. Their system seems to have been a mixture of Christian elements, Jewish legalism, and Essenian asceticism, with a mixture of astrology and magic. Perhaps the chief object of the sect was to mingle Judaism and Christianity, so that the Hebrews of that day could embrace the new doctrines without entire repudiation of their old belief. The fullest account of the Book of Elkesai is found in the *Philosophoumena* of Hippolytus. Consult Brandt, *Elchasai* (Leipzig, 1912), and Rainy, *The Ancient Catholic Church* (New York, 1902).

EL KHARGEH, ēl-kār'ge. See KHARGEH, EL.

ELKHART. A city in Elkhart Co., Ind., 101 miles by rail east by south of Chicago, at the confluence of the St. Joseph and Elkhart rivers, and on the Lake Shore and Michigan Southern, the St. Joseph Valley, the Chicago, South Bend, and Northern Indiana, and the Cleveland, Cincinnati, Chicago, and St. Louis railroads (Map: Indiana, F 1). A large dam and power house, erected in 1913 at a cost of \$750,000, furnishes abundant power for its industries, which include railroad shops, musical instrument factories, automobile works, bridge and iron works, and establishments for the manufacture of carriages, invalid tables, machinery, go-carts, corsets, telephone supplies, furniture, brass sundries, gas generators, paper boxes, rubber, and paper. The city has a Carnegie library and a fine high-school building. The control of the government is vested almost entirely in the mayor, and there is a city council.

Pop., 1900, 15,184; 1910, 19,282; 1914 (U. S. est.), 21,028.

ELKHORN. A city and the county seat of Walworth Co., Wis., 54 miles southwest of Milwaukee, on the Chicago, Milwaukee, and St. Paul Railroad (Map: Wisconsin, E 6). There is a public library, and there are extensive fair grounds owned and operated by residents of the county. It is the centre of a fertile agricultural region and has large dairying interests and a creamery and condensed-milk plant. The electric-light plant and water works are owned by the municipality. Pop., 1890, 1,447; 1900, 1,731; 1910, 1,707.

ELK HORN, BATTLE OF. See PEA RIDGE, BATTLE OF.

ELKHORN RIVER. A tributary of the Platte River, Neb. The main stream rises in Brown County and the north fork in Knox County (Map: Nebraska, F 2). They unite in Madison County, and the stream flows southeast, joining the Platte in Sarpy County, in the eastern part of the State, after a course of about 200 miles. The Frémont, Elkhorn, and Missouri Valley Railroad runs through this valley. The largest tributary is Logan Creek.

ELKIN, WILLIAM LEWIS (1855-). An American astronomer. He was born in New Orleans, was educated at the Royal Polytechnic School, Stuttgart, Germany, and at the University of Leipzig. His astronomical investigations at the Royal Observatory, Cape of Good Hope, in 1882-83 on the parallaxes of southern stars, which investigations he undertook in association with Sir David Gill, were important. This work was supplemented in 1887-88 by his determination of the parallaxes of a number of the brightest northern stars. From 1896 to 1910 he was director of the Yale Observatory. He has published the results of many searches in the *Transactions of the Yale Observatory* and other astronomical journals.

ELKINS. A city and the county seat of Randolph Co., W. Va., 113 miles southwest of Cumberland, Md., on the Western Maryland and the Coal and Coke railroads (Map: West Virginia, E 3). It is the seat of Davis and Elkins College and has an Odd Fellows home, two hospitals, and an orphans' home. Its chief industries are tanning, locomotive and car repairing, and the manufacture of boxes, and extracts. Under a charter governed by a mayor, chosen annually, and a unicameral council. The water works are owned by the city. Pop., 1900, 2,016; 1910, 5,260.

ELKINS, STEPHEN BENTON (1841-1911). An American capitalist and politician. He was born in Perry Co., Ohio, graduated at the University of Missouri (Columbia) in 1860, was admitted to the Missouri bar in 1864, removed to New Mexico, and in the same year was elected to the Territorial Legislature. Subsequently he became a district attorney and Attorney-General of the Territory and United States District Attorney. From 1873 to 1877 he was delegate to Congress from New Mexico. Later he removed to West Virginia and there married the daughter of Henry Gassaway Davis (q.v.), acquired large business interests in West Virginia, particularly in the coal industry and railways, and became vice president of the West Virginia Central and Pittsburgh Railway. From 1891 to 1893 he was Secretary of War in President Harrison's cabinet, and in 1894 he was elected to the United States Senate, thereafter

being twice reelected. The Elkins Railway Law of 1903 bore his name. His son Davis Elkins succeeded him ad interim in the Senate in 1911 by appointment of the Governor.

ELK RIVER. See **ATHABASCA RIVER.**

ELKS, BENEVOLENT AND PROTECTIVE ORDER OF. A benevolent fraternal society, organized in the city of New York, Feb. 16, 1868, as the outgrowth of a social club known as the Jolly Corks, composed principally of members of the theatrical profession. Its first regular organization was New York Lodge No. 1. The Grand Lodge of the order was incorporated March 10, 1871, as chap. xix of the laws of that session, and the past officers of New York Lodge No. 1 were made the first members of the Grand Lodge under the act of incorporation. The power to form subordinate lodges was given to the Grand Lodge on March 12, 1871. Charters were issued to New York No. 1 and Philadelphia No. 2. The third lodge was incorporated April 18, 1876, in San Francisco, and subsequently lodges were formed at Cincinnati, Sacramento, Baltimore, St. Louis, Boston, Pittsburgh, Indianapolis, Providence, Washington, Denver, Cleveland, in the order named, and in other cities. The order, in addition to assisting its own members, has been a liberal contributor to the relief of suffering in national calamities like the Chicago and Boston fires, the Galveston and Johnstown floods, and the California earthquake disaster; it has since its institution dispensed nearly \$3,000,000 in such causes. The number of lodges in 1914 was 1309, and subordinate lodges have been established in Skaguay and Juneau in Alaska, Honolulu and Hilo in the Hawaiian Islands, and Manila in the Philippines. Membership in the order can be acquired only by white male citizens of the United States of the age of 21 and upward, of good moral character; only one lodge can be instituted in any one city, and such city must have a population of at least 5000, and each lodge is given complete jurisdiction over all residents within said corporation.

One of the unique features of the order, which attracts the attention of the outside world to its internal organization, is the annual memorial service for the dead of the order, held by every lodge on the first Sunday in December of each year. This is termed the "Sacred Session of the Order." The similar term "lodge of sorrow" is applied only to funerals. The membership in 1914 was upward of 410,000, and the society owned property and cash to the extent of about \$1,000,000. The benefits disbursed in 1913 were \$516,176. The *Elks Antler*, published monthly in New York City, is the order's official paper. Consult C. E. Ellis, *Authentic History of the Benevolent and Protective Order of Elks* (Chicago, 1910).

ELKTON. A town and the county seat of Cecil Co., Md., 50 miles northeast of Baltimore, on the Philadelphia, Baltimore, and Washington Railroad, and on the Elk River, at the head of navigation (Map: Maryland, H 1). It has pulp and textile mills, fertilizer works, a hosiery mill, and boat yards. Elkton was first settled in 1681 and incorporated in 1787. It has adopted the commission form of government. Pop., 1900, 2542; 1910, 2487.

ELL (AS. *eln*, Icel. *alin*, Goth. *aleina*, OHG. *elina*, *elna*, Ger. *Elle*; connected with Lat. *ulna*, Gk. *ὤλερν*, *ὀλενέ*, forearm). An obsolete measure of length. It was originally taken in some

vague way from the arm and hence has been used to denote very different lengths. The Latin *ulna* appears to have denoted sometimes the measure from the elbow to the tips of the fingers and sometimes that between the outstretched hands. The English ell, as a measure of cloth, is equal to five-quarters of a yard.

ELLAGIC ACID, *el-laj'ik* *as'id* (arbitrarily transposed from Fr. *galle*, gallnut, as being a derivative of gallic acid), $C_{14}H_6O_8$. A white crystalline substance contained in the bezoar stones found in the antelope and other animals. Its principal occurrence, however, is in tannin matters containing ellagitannin. It was discovered in oak galls by Chevreul in 1828. It may be prepared from divi-divi (*Coscalpinia coriaria*, Willd.) by boiling the tannin extract with dilute acids and recrystallizing the precipitated ellagic acid from pyridine. Löwe reproduced ellagic acid synthetically by oxidizing gallic acid. In 1909 Rupe showed that ellagic acid may be readily prepared by the addition of sodium nitrite to gallic acid dissolved in sulphuric acid. Ellagic acid plays a rôle of some importance in the tanning process. Its constitution is in all probability represented by the formula

ELLAND, *el'land*. A town in the West Riding of Yorkshire. It is in the Calder, 2½ miles south of Leeds (Map: England, E 3). Its chief industries are the manufacture of cottons, woollens, iron, paper, and fire clay. Pop., 1901, 10,412; 1911, 10,076.

ELLENBOROUGH, EDWARD LAW, first **BARON** (1750-1818). An English lawyer and jurist, Lord Chief Justice from 1802 to 1818. He was born at Great Salkeld, Cumberland, was educated at the Charterhouse and at Peterhouse College, Cambridge, was a fellow of Trinity, and studied law at Lincoln's Inn. He began to practice law as a special pleader in 1775, was called to the bar in 1780, and made a King's counsel in 1787. In the year 1788 he became leading counsel for Warren Hastings in his trial before the House of Lords. In 1793 he was appointed Attorney-General for the County Palatine of Lancaster, and as one of the crown attorneys assisted in many famous trials, including those of Lord George Gordon and Horne Tooke. In 1801 he was appointed Attorney-General in the House of Commons, was knighted, and was elected to the House of Commons. In April, 1802, he was appointed to succeed Lord Kenyon as Lord Chief Justice of England, at the same time being raised to the peerage under the title of Baron Ellenborough. His entering the ministry of "All the Talents" in 1806 was much criticized, the only precedent of a judge holding political office being that of Lord Mansfield. His fame as a legislator rests for the most part on the Ellenborough Act—since repealed—by which 10 new capital felonies were created. Although a man of great legal knowledge and sterling integrity, he was quick-tempered and of violent prejudices, characteristics which greatly affected his standing as a jurist. Originally a Whig, he had changed sides after the French Revolution. Consult Campbell, *Lives of the Chief Justices of England*, vol. iii (London, 1857).

ELLENBOROUGH, EDWARD LAW, first EARL OF (1790-1871). An English statesman, son of Baron Ellenborough. He was educated at Eton and at St. John's College, Cambridge, where he . . . 1809. In 1813 he married Lord . . . sister and entered Parliament. . . Privy Seal in the Duke of Wellington's administration (1828-29) and in 1841 was appointed Governor-General of India. His policy was displeasing to the directors of the East India Company, and he was recalled. The ministry, however, stood by him, and he was created an earl and a viscount. In the Derby administration of 1858 he was President of the Board of Control. Having permitted a dispatch to be made public in which he had administered a severe and taustic rebuke to Lord Canning, Governor-General of India, he was compelled to resign. He remained out of office until his death, though he continued to be the foremost orator in the House of Lords.

ELLENRIEDER, ɛl'ɛn-rē'dēr, MARIE (1791-1863). A German portrait and historical painter, born at Constance. She studied at the Academy of Munich, under Einsle, the painter of miniatures, and completed her education at Rome, under Overbeck. She resided at Constance and in 1840 was appointed court painter to the Grand Duke of Baden. She belongs to the religious and romantic school of the Nazarenes, and painted chiefly portraits and altarpieces. Among the best are a "Virgin and Child" (1824); a "St. Felicitas," in possession of the King of England; "The Stoning of St. Stephen"; "Mary in a Bower of Roses," in the Museum of Karlsruhe, which possesses a number of her works. Her heads of women and children are graceful, but her color is gray, dull, and sombre. She also etched 24 plates after Overbeck, Rembrandt, Titian, and others.

EL/LENSBURG. A city and the county seat of Kittitas Co., Wash., 119 miles by rail east-southeast of Seattle, on the Northern Pacific and the Chicago, Milwaukee, and St. Paul railroads, and on the Yakima River (Map: Washington, E 4). Ellensburg contains a public library and a State normal school. The city is in an extensively irrigated region, which has valuable deposits of coal, iron, and gold, and produces live stock and dairy and orchard products. There are grist and saw mills, a glove factory, creameries, and a woolen mill. The electric-light plant and water works are owned by the city. Pop., 1900, 1737; 1910, 4209.

EL/LENVILLE. A village in Ulster Co., N. Y., 28 miles southwest of Kingston, on the New York, Ontario, and Western Railroad (Map: New York, A 1). Picturesquely situated in the midst of the Shawangunk Mountains, Ellenville is a popular summer resort. It has finely shaded streets and is near several places of interest, including Mount Meehaha, the Ice Caves, Sun Ray Spring, and many beautiful waterfalls. Its chief industrial establishments are manufactories of pocket cutlery, handkerchiefs, and shirt waists, and concrete stone and paint works. The village owns its water works. Pop., 1900, 2879; 1910, 3114.

EL/LERY, ROBERT LEWIS JOHN (1827-1908). An English astronomer, born at Cranley, Surrey. He was educated for the medical profession, but became interested in astronomy and meteorology. In 1851 he went to Australia, where two years later he erected an astronomical observatory at Williamstown, near Melbourne,

Victoria, and from 1856 to 1874 he conducted the geodetic survey of that colony. Under his direction the observatory founded by him (subsequently removed to Melbourne) published about 30 volumes of meteorological, and several volumes of astronomical, observations. He was one of the founders of the Royal Society of Victoria, the presidency of which he filled for 23 years. He retired from public life in 1895.

ELLERY, WILLIAM (1727-1820). A signer of the Declaration of Independence. He was born in Newport, R. I., . . . t Harvard in 1747, was a merchant . . . for several years, then acted as naval agent for the Colony, and afterward practiced law. From 1776 to 1786, with the exception of 1782, he was a member of the Continental Congress, and served on the Marine Committee and the Board of Admiralty. He was Chief Justice of Rhode Island in 1785. In 1786 he became commissioner of the Continental Loan Office for Rhode Island, and from 1790 until his death was collector of customs for the district of Newport. Consult Sparks's *Library of American Biography*, vol. vi (Boston, 1836).

ELLESMERE, ɛlz'mēr, FRANCIS EGERTON, first EARL OF (1800-57). An English politician, second son of the Duke of Sutherland. He was born in London, studied at Eton and Christ Church, Oxford, entered the House of Commons in 1822 and spoke for free trade, and was Chief Secretary for Ireland from 1828, to 1830, when he became Secretary of State for War. In 1833 he assumed the name of Lord Francis Egerton, in lieu of his patronymic, Leveson-Gower, and in 1846 he was created Viscount Brackley and Earl of Ellesmere. In politics a Liberal Conservative, he spoke in behalf of free trade 20 years before Sir Robert Peel embraced the cause. He was a writer of graceful poems and plays; a translator of Goethe's *Faust*, of Schiller, of Körner, and of Dumas's *Henri III*; the author of a *Guide to Northern Archaeology* (1848); and a munificent patron of the arts. His valuable collection of pictures was placed by him in a gallery open to the public. He was lord rector of Aberdeen University (1841), president of the Royal Geographical Society, and a patron of Agassiz. His *Personal Reminiscences of the Duke of Wellington* was edited with a memoir by his daughter (New York, 1904).

ELLESMERE LAND. The southern part of the large body of land lying north of Jones Sound and west of northern Greenland, from which Ellesmere Land is separated by Smith Sound (Map: America, North, K 2). This land, with its fringing islands, forms the northernmost extension of the Arctic archipelago of North America. Ellesmere Land is an uninhabited region, almost entirely covered by glacial ice caps. It was first seen by William Baffin, in 1616. Up to 1899 it was thought to be separated from Grinnell Land, which lies to the north, by Hayes Sound; but the explorations of Peary in that year proved Hayes Sound to be a mere inlet of Kane Basin. The most extensive explorations are those of Otto Sverdrup (1898-1902), who discovered the unknown west coast and adjacent islands. Consult Sverdrup, *Four Years in the Arctic Regions* (2 vols., New York, 1904).

EL/LET, CHARLES (1810-62). An American engineer, born in Penn's Manor, Bucks Co., Pa. He began life as a surveyor and completed his engineering studies at the Ecole Polytechnique

in Paris. After serving as an assistant engineer on several railroads, he was appointed chief engineer of the James and Kanawha Canal. In 1841-42 he planned and constructed the wire suspension bridge across the Schuylkill at Fairmount, Pa., the first bridge of the sort to be built in America. He also built the suspension bridge at Niagara below the Falls and a large railway suspension bridge for the Baltimore and Ohio Railroad at Wheeling, W. Va. He was president of the Schuylkill Navigation Company in 1846 and became interested in steamboat construction. At the beginning of the Civil War he was commissioned a colonel of engineers by the Secretary of War and set to work to construct a fleet of rams after his own plans. With a squadron of nine rams he attacked a fleet of Confederate gunboats off Memphis, Tenn., on June 6, 1862, and sank and disabled several of them. During the engagement, however, he received a wound from the effects of which he died. Of his numerous writings, the most important are: *Physical Geography of the Mississippi Valley* (1851); *The Mississippi and Ohio Rivers* (1853); *Coast and Harbor Defenses* (1855); *The Army of the Potomac, and its Mismanagement* (1861).

ELLET, ELIZABETH LUMMIS FRIES (1818-77). An American author, born at Sodus Point, N. Y. Besides contributing to periodicals, she was the author of *The Characters of Schiller* (1842); *Women of the American Revolution* (1851); *Court Circles of the Republic*, with Mrs. R. E. Mack (1869).

ELLICE (əl'is) **ISLANDS**, or **LAGOON ISLANDS**. A low-lying group of islands in the Pacific, between lat. 5° and 11° S. and long. 176° and 180° E. (Map: Australasia, K 3). They are of coral formation, extending over more than 360 miles, but occupying an area of less than 15 square miles. Guano, yams, fruit, coconuts, and copra are the chief products. They belong to Great Britain, having formed, since 1892, an administrative dependency of the Fiji group. They were discovered in 1781 by Maurelle. Pop. (mainly Christianized Polynesians), 1911, 3084.

ELLICHPUR, əl'ich-poor. A town in the Amraoti District of Berar, British India, on the Bichan, 32 miles northwest of Amraoti (Map: India, C 5). It is a station of the Imperial Service troops and has manufactures of cotton goods and carpets. It is a large market for logs and lumber. Pop., 1891, 26,637; 1901, 26,082; 1911, 13,909.

ELLCOTT, ANDREW (1754-1820). An American civil engineer, born in Bucks Co., Pa. In 1789 he was appointed by Washington to survey the lands in western Pennsylvania and New York, near Lake Erie, and in the same year made the first accurate measurements of Niagara Falls and River. In 1790 he was engaged in surveying and laying out the new city of Washington, was appointed Surveyor-General of the United States in 1792, and in 1796 was one of the commissioners on the part of the United States to determine the boundary between this country and the Spanish territory. From 1801 to 1808 he was secretary of the Pennsylvania State Land Office, and from 1812 until his death held the chair of mathematics at the West Point Military Academy. He published a *Journal* in 1803.

ELLCOTT, CHARLES JOHN (1819-1909). An English clergyman and educator. He was born

at Whitwell, near Stamford, graduated at Cambridge (St. John's) in 1841, and for 10 years was rector of Pilton, Rutlandshire, but in 1858 became professor of New Testament exegesis in King's College, London, and in 1860 Hulsean professor of divinity at Cambridge. In 1861 he was made dean of Exeter and in 1863 Bishop of Gloucester and Bristol. When this see was divided in 1897, he became Bishop of Gloucester; he resigned his diocese in 1904. He became chairman of the New Testament Revision Committee in 1881. He defended the revision in various pamphlets, notably one (1882) in co-operation with Archdeacon Edward Palmer. His most important work is his *Critical and Grammatical Commentaries* on many of the Epistles (1854-58; 1887), and he edited a *Handy Commentary* on the New Testament (3 vols. and 13 vols., 1877-79). Among his other publications are: *Treatise on Analytical Statics* (1851); the (Hulsean) *Lectures on the Life of Our Lord Jesus Christ* (1860); and *Aids to the Faith* (1861), a reply to Jowett in *Essays and Reviews*.

ELLCOTT CITY. A city and the county seat of Howard Co., Md., 9 miles (direct) west of Baltimore, on the Patapsco River, and on the Baltimore and Ohio Railroad (Map: Maryland, F 2). It has manufactures of flour, cotton, silk, and woolen goods. Rock Hill College (Roman Catholic) was opened here in 1857, and the city contains a sanitarium. Founded in 1772, Ellicott City was incorporated in 1867. Pop., 1900, 1331; 1910, 1151.

ELLIOT, ARTHUR RALPH DOUGLAS (1846-). An English lawyer and author, a son of the third Earl of Minto. He was educated at Edinburgh University and at Trinity College, Cambridge; was member of Parliament from 1880 to 1892 and from 1898 to 1906; and served as Financial Secretary to the Treasury during 1903. From 1895 to 1912 he was editor of the *Edinburgh Review*. His publications include: *Criminal Procedure in England and Scotland* (1878); *The State and the Church* (1881; 2d ed., 1899); *Life of the First Viscount Goschen* (1911).

ELLIOT, DANIEL GIRAUD (1835-). An American ornithologist. He was born in New York and received an academic education. From 1856 to 1878 he traveled extensively in Europe, Africa, and Asia Minor, but afterward confined his travels and investigations principally to America. In 1896 he led an expedition into East Africa in the interest of the Field Museum, Chicago, and on his return became curator of zoölogy for that institution. In 1898 he had charge of an expedition sent under the same auspices to explore the Olympic Mountains in the State of Washington. He was the founder and a president of the American Ornithological Union and a vice president of the Zoölogical Society of France. He was decorated 10 times by European governments for work in scientific fields. His extensive scientific writings include treatises and monographs on *Family of the Grouse* (1865); *Family of the Pheasants* (1871-72); *Family of the Hornbills* (1877-82); *Birds of North America* (1897); *The Land and Sea Mammals of Middle America and the West Indies* (1894); *Wild Fowl of the United States and British Possessions* (1898); *North American Shore Birds* (1895); *Gallinaceous Game Birds of North America* (1897); *Synopsis of the Mammals of North America and the Adjacent Seas*

(1901); *Catalogue of Mammals in the Field Columbian Museum* (1906); *A Review of the Primates*, vols. i-iii (1913).

ELLIOT, GILBERT. See MINTO, EARL OF.

ELLIOTSON, JOHN (1791-1868). An English physician, born in London and educated at Edinburgh and Cambridge. In 1829 he delivered before the Royal College of Physicians his valuable Lumley lectures on diseases of the heart (published in 1830), and in 1831 he was called to the chair of clinical medicine of London University. The establishment of the University College Hospital, of which he became chief physician in 1834, was due chiefly to his influence, and in his practice there he may be said to have been the first to demonstrate the importance of clinical teaching. Auscultation and the use of the stethoscope were also introduced by him. Deeply interested in the study of mesmerism, he established, in 1849, a mesmeric hospital where hypnotic treatment is said to have been applied successfully. To him W. M. Thackeray dedicated his *Pendennis*. He was the founder and first president of the Phrenological Society and president of the Royal Medical Society of London. Besides numerous contributions to periodicals, he published a translation of Blumenbach's *Elements of Physiology* (2d ed., 1828) and wrote: *Cases of the Hydrocyanic or Prussic Acid* (1820); *Lectures on Diseases of the Heart* (1830); *Principles and Practice of Medicine* (1839); *Human Physiology* (1840); *Surgical Operations in the Mesmeric State without Pain* (1843).

ELLIOTT, AARON MARSHALL (1846-1910). An American Romance philologist, born at Wilmington, N. C. He graduated from Haverford College in 1866 and from Harvard in 1868 and also studied in France, Italy, Spain, Germany, and Austria. At Johns Hopkins University he served as an associate in Romanic languages (1876-84), associate professor (1884-92), and professor (1892-1910). He became known for his researches in mediæval French languages and gave special attention to the works of Marie de France. For seven years he was secretary of the Modern Language Association of America. In 1907 he was decorated with the cross of the Legion of Honor.

ELLIOTT, CHARLES (1792-1869). An American Methodist Episcopal clergyman. He was born in County Donegal, Ireland, and preached there for two years before emigrating to America in 1815. He was superintendent of missions among the Wyandot Indians, presiding elder of the Ohio district, professor of languages in 1827-31 at Madison College (Uniontown, Pa.), presiding elder of the Pittsburgh district, and editor of various Methodist periodicals. From 1856 to 1860 and again from 1864 to 1867 he was president of the Iowa Wesleyan University and professor of biblical literature. His reputation as a scholar rests chiefly upon his *Delineation of Roman Catholicism* (2 vols., 1841). Among his further publications are: *Treatise on Baptism* (1834); *Indian Missionary Reminiscences* (1850); *The Great Secession* (1852), a history of the division of the Methodist Episcopal church in 1845 on account of slavery; *South-western Methodism* (1868).

ELLIOTT, CHARLES LORING (1812-68). An American portrait painter. He was born at Auburn, N. Y., and studied in New York City under Trumbull and Quidor. After practicing portrait painting in New York State for 10 years

he took up his residence in New York City in 1845 and the following year was elected to the National Academy of Design. Elliott was the best portraitist of his day, and although he never went abroad his technique is neither provincial nor uncertain. His method is mature, his drawing firm, his color fresh and clean, and his likenesses excellent, though somewhat lacking in sentiment. He is said to have painted over 700 portraits, mostly heads, as he had little idea of the composition of large canvases. Among his sitters were Fenimore Cooper, Fitz-Greene Halleck, Fletcher Harper, A. B. Durand (the Corcoran Gallery, Washington), and Governor Bouck (City Hall, New York). There are other portraits by him in the New York City Hall, the State Library at Albany, and four examples in the Metropolitan Museum, New York. He also painted figure pieces, including "Don Quixote" and "Falstaff," and one landscape, "The Head of Skaneateles Lake."

ELLIOTT, EBENEZER (1781-1849). An English poet, known as the Corn-Law Rhymmer. He was born at Masborough, Yorkshire, England. In 1821 he entered the iron trade at Sheffield and was very successful and in 1841 retired to an estate which he had purchased at Great Houghton, near Barnsley. His best productions are *The Village Patriarch* (1829), *The Splendid Village*, and the famous *Corn-Law Rhymes* (1831). Elliott followed Crabbe, but with more fire and depth of feeling, in depicting the condition of the poor as miserable and oppressed, tracing most of the evils he deplores to the social and political institutions of the country, especially to the Corn Laws. A new edition of his works, revised and edited by his son, Edwin Elliott, was published in London (1876). Consult Watkins, *Life, Poetry, and Letters of Ebenezer Elliott* (London, 1850), and a critical edition of the man by Thomas Carlyle in the *Edinburgh Review* (1832).

ELLIOTT, EDWARD CHARLES (1874-). An American educator, born in Chicago. After graduating from the University of Nebraska in 1895, he studied at Jena and Columbia universities. From 1898 to 1903 he was superintendent of the Leadville (Colo.) schools, and at the University of Wisconsin he was associate professor of education in 1905-07, professor after 1907, and also director of the pedagogical seminar after 1909. He also conducted special investigations for the United States Bureau of Education in 1906-10, for the New York Board of Education in 1911-12, and for the State of Vermont in 1913. His publications include: *Some Fiscal Aspects of Public Education in American Cities* (1905); *State School Systems* (1904; 3d ed., 1910); *Legislation upon Industrial Education in the United States* (1910); *City School Supervision* (1914).

ELLIOTT, SIR HENRY MEERS (1808-53). An English historian. After finishing his studies at Oxford, at an early age he entered the service of the East India Company and was secretary to the Governor-General in 1847. Two years later he negotiated the important treaty with the native chiefs regarding the settlement of the Punjab and Gujarat. He died at the Cape of Good Hope on his way back to England in 1853. His principal literary productions are: *Supplement to the Glossary of Indian Terms*, of which only the first volume appeared (1846; enlarged ed. by Beames, 1869); *Bibliograph-*

ical Index to the Historians of Mohammedan India, vol. i (1849), a work in which the author enters upon an extensive biographical and critical discussion of more than 200 Arabic and Persian historians, but which was not completed; and the *History of India as told by its own Historians*, ed. by John Dowson (8 vols., 1866-77; a *Sequel* by Sir E. C. Bailey, 1886). This latter is a valuable contribution to the history of Mohammedan rule in India.

ELLIOTT, HOWARD (1860-). An American railroad president, born in New York City. He graduated from Lawrence Scientific School (Harvard) in 1881. After serving in several less important capacities with the Chicago, Burlington and Quincy Railroad until 1887, he then became general freight and passenger agent of the St. Louis, Keokuk, and Northwestern Railway—a part of the Burlington System—and later he was general freight agent (1891-96) of the whole system, general manager (1896-1902), and second vice president (1902-03). He was president of the Northern Pacific Railway Co. from 1903 to 1913, and in the latter year succeeded Charles S. Mellen as president of the New York, New Haven, and Hartford; but he resigned this office before the end of the year and became chairman of the board of directors.

ELLIOTT, JESSE DUNCAN (1782-1845). An American naval officer. He was born in Maryland, was educated at Carlisle, Pa., studied law, and in 1804 entered the navy as a midshipman. In October, 1812, he captured two British brigs, the *Detroit* and the *Caledonia*, near Fort Erie (q.v.), the first naval success for the Americans on the Great Lakes. At the capture of York (now Toronto), in April, 1813, he commanded the *Madison*, and in the battle of Lake Erie, September, 1813, the *Niagara*, being second in command to Perry. His conduct during the battle was the subject for many years of considerable controversy. In October, 1813, he succeeded Perry in command of the Lake Erie fleet. He afterward commanded the sloop of war *Ontario* under Decatur during the war against Algiers in 1815, was raised to the rank of captain in 1818, and commanded the West India squadron and the Charlestown Navy Yard. In 1840, after having commanded the *Constitution* in the Mediterranean squadron for several years, he was tried by court-martial and was suspended from duty for four years. In October, 1843, however, he was restored to the service and was placed in command of the Philadelphia Navy Yard. For discussions of his conduct in the battle of Lake Erie, consult: Jarvis, *A Biographical Notice of Commodore Jesse D. Elliott* (Philadelphia, 1835); Burges, *Battle of Lake Erie, with Notices of Commodore Elliott's Conduct in that Engagement* (ib., 1839); Cooper, *Battle of Lake Erie* (Cooperstown, 1843); Bancroft, *History of the Battle of Lake Erie, and Miscellaneous Papers* (New York, 1891).

ELLIOTT, JOHN (1858-). An American mural and portrait painter. He was born in England, on the Scottish border, of a well-known family, and studied at the Julian Academy under Carolus Duran, and at Rome under Villegas. One of his earliest and most characteristic decorative pieces is "The Vineage," a ceiling and frieze in the house of Mrs. Potter Palmer, Chicago. This was followed by a ceiling for the Boston Public Library (1894-1901), entitled "The Triumph of Time," decoratively treated, yet of great depth and airiness.

In 1908 he completed his greatest achievement, the mural painting "Diana of the Tides," in the New National Museum, Washington. His decorations are characterized by luminous color, subtle handling of light, and clever blending of the real and ideal. Elliott is also noted as a portrait painter, especially in red chalk, pastel, and silver point, in which mediums he displays a delicate and subtle technique. Among his best portraits are those of his mother-in-law, Julia Ward Howe, in red chalk (Metropolitan Museum, New York); King Humbert of Italy, in silver point (owned by Queen Margherita); Lord Ava; The Marquis of Winchester; and General Wauchope. His figure subjects include two versions of "Dante in Exile" (one owned by Queen Margherita) and a pastel study of Dante (Mrs. David Kimball), which has become world famous. His illustrations for fairy tales also deserve mention. For his distinguished services to the earthquake sufferers at Messina, he received medals from the Italian government and the American Red Cross Society.

ELLIOTT, MAXINE (1871-). An American actress, born at Rockland, Me., daughter of Thomas and Adelaide Dermot. Her first serious rôle was as Felicia Umfraville, with E. S. Willard in *The Middleman*, in 1890. Afterward she played with Willard in *The Professor's Love Story* and other pieces. With Daly's company she went to London in 1895, playing in Shakespearean parts as well as in light comedy. In 1896 she joined N. C. Goodwin, with whom, in 1898, she played in Clyde Fitch's *Nathan Hale*. In 1898 she was married to Goodwin, and in 1900 they appeared with much popular success in H. V. Esmond's *When We Were Twenty-one*. In 1903 she appeared as a "star" in Clyde Fitch's *Her Own Way*. After this she continued to "star" successfully in various light comedies.

ELLIOTT, SAMUEL MACKENZIE (1811-73). An American physician, born at Inverness, Scotland. He was educated at the Royal College of Surgeons in Glasgow. In 1833 he went to the United States and continued his medical studies in Philadelphia and Cincinnati. In 1835 he settled in New York City and soon gained great reputation as an oculist. He served in the Civil War as lieutenant colonel of the Highland Guard and was wounded in the first battle of Bull Run. Subsequently he was brevetted brigadier general.

ELLIOTT, SARAH BARNWELL (?-). An American novelist, daughter of Stephen Elliott (1806-66), first Bishop of Georgia. Her more noteworthy volumes of fiction are: *The Felmeres* (1879); *Jerry*, a pathetic story of "poor-white" life in the Tennessee mountains, originally published serially in *Scribner's Magazine*, later translated into German, and republished in Australia; *The Durket Sperret*, a realistic story also of the Tennessee mountaineer; *An Incident and Other Happenings* (1899); *The Making of Jane* (1901). She also wrote an excellent biography of *Sam Houston* (1900) for the "Beacon Biographical Series" and many short stories, chiefly of Southern life.

ELLIOTT, STEPHEN (1771-1830). An American naturalist. He was born at Beaufort, S. C., graduated at Yale in 1791, and was a member of the State Legislature from 1793 until 1812. He assisted in organizing the Literary and Philosophical Society of South Carolina and was for a time its president. He was also

one of the founders of the State medical college, in which for some years he was professor of natural history and botany. From 1812 to his death he was president of the Bank of the State. He published *The Botany of South Carolina and Georgia* (2 vols., 1821-24) and was for a time the editor of the *Southern Review*.

ELLIPSE (Lat. *ellipsis*, from Gk. ἔλλειψις, *elleipsis*, omission, from ἔλλειπειν, *elleipein*, to

omit, from ἐν, *en*, in + λείπειν, *leipein*, to leave). An important geometric figure, representing the approximate shape of the planetary orbits. It is one of the conic sections (q.v.) and received its name from Apollonius (q.v.). It is a curve of the second order and second class (see CURVE) and may be defined as the locus of a point (*P*), the sum of whose distances from two fixed points are constant. The two fixed points are called the foci (*F* and *F'*); the diameter drawn through them is called the major axis, and the perpendicular bisector of this diameter the minor axis. It is also defined as the locus of a point which moves so that the ratio of its distance from a fixed point, called the focus, to its distance from a fixed line (*DD'*), called the directrix, is constant and less than unity; the constant ratio is called the *eccentricity* of the ellipse and is equal to the ratio of the distance between the foci to the

major axis. The limit of the ellipse, as the eccentricity approaches 0 and the foci approach coincidence, is the circle. There are various contrivances for describing an ellipse, called *ellipsographs*, or *elliptic compasses*. The simplest method is to fix the two ends of a thread to

pins at the foci and make a pencil move in the plane, keeping the thread taut. The end of the pencil will trace an ellipse whose major axis is equal to the length of the thread. The Cartesian equation of the ellipse placed symmetrically with respect to the axis of coordinates

(q.v.) is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, *a*, *b* being the semimajor and semiminor axes respectively. The eccentricity is $e = \frac{\sqrt{a^2 - b^2}}{a}$. The polar equation of the

ellipse is $r = \frac{P}{1 + e \cos \theta}$, where the parameter $P = \frac{b^2}{a}$. The centre *O* bisects all chords passing through it; each diameter of a pair of conjugate (q.v.) diameters bisects all chords parallel to the other; and the focal chord parallel to the directrix is called the *latus rectum*. From the equation of the ellipse, by means of the integral calculus, its area is shown to be πab . The length of its circumference is approximately

$$2\pi a \left(1 - \frac{e^2}{2^2} - \frac{1.3e^2}{2^2 \cdot 4^2} - \frac{1.3^2 \cdot 5e^2}{2^2 \cdot 4^2 \cdot 6^2} - \dots \right).$$

There are several special kinds of ellipses, for the names and equations of which, consult Brocard, *Notes de bibliographie des courbes géométriques* (Bar-le-Duc, 1897).

ELLIP'SIS (Lat., from Gk. ἔλλειψις, *elleipsis*, omission). A term used in grammar and rhetoric to signify the omission of a word necessary to complete the expression or sentence in its usual form. The object of ellipsis is brevity and impressiveness. See SYNTAX, FIGURES OF.

ELLIP'SOID (from Gk. ἔλλειψις, *elleipsis*, ellipse + εἶδος, *eidos*, form). A kind of solid, bounded by a surface of the second order, the spheroid being a special case, as stated below. The latter has a peculiar interest because the form of the earth is spheroidal. The Cartesian equation of an ellipsoid referred to its centre as origin, and its axes as axes of coordinates (q.v.), is $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$, where *a*, *b*, *c* are the semi-axes. By giving the value 0 successively to *x*, *y*, *z*, the equations of three ellipses are obtained, which are the sections of the ellipsoid, made by the respective coordinate planes. If any two of the quantities *a*, *b*, *c* are equal, one of the three sections is a circle, and the ellipsoid becomes an *ellipsoid of revolution*. The surface formed by the revolution of an ellipse about its major axis is called a *prolate* spheroid, and that formed by the revolution about the minor axis is called an *oblate* spheroid, the latter being the general form of the earth. The term is often applied to the solid inclosed by the surface above defined. Ellipsoids play an important part in the theory of inertia. If on an line *l* through the origin *O*, a length *OP* be laid off, inversely proportional to the square root of the moment of inertia *I* of the line with respect to the given mass *m*, the locus of the point *P* will be a quadric surface called the *ellipsoid of inertia*, or *momental ellipsoid*, of the point *O*. The polar reciprocal (see POLE AND POLAR) of the momental ellipsoid with respect to a certain sphere is called the *ellipsoid of gyration*, or the *reciprocal ellipsoid*.

ELLIP'TIC FUNCTIONS. See FUNCTIONS.

ELLIS, ALEXANDER JOHN (1814-90). An English philologist and mathematician, born at

Hoxton, London, and educated at Eton and Trinity College, Cambridge. He was born under the surname Sharpe, but changed it to Ellis by royal license in 1825. He began the study of law in the Middle Temple, but gave it up for mathematics, first attracting attention by a translation of Ohm's *Geist der mathematischen Analysis* in 1847. It was as a phonologist and, however, that Ellis was best known. . . . himself with Sir Isaac Pitman, with whom he formulated a system of printing which he called "phonotypy," which added several new letters to the alphabet corresponding to sounds used in spoken language. His work formed the basis for all modern English phonetics in that he was the first to reduce this study to a science. His studies in phonology led him naturally to a study of philology, and he took high rank as an authority on both early English pronunciation and modern English dialects. His greatest work in this field was entitled *On Early English Pronunciation, with Special Reference to Shakspere and Chaucer*, which was published at intervals between 1869 and 1889. Another field in which Ellis achieved distinction was in the scientific theory of music, to the literature of which he contributed *The Sensations of Tone as a Physiological Basis for the Theory of Music* (1875), based on a German work by Helmholtz, and *The History of Musical Pitch* (1880). His other works include: *Horse Taming* (1842); *Phonetics* (1844); *A Plea for Phonetic Spelling* (1848); *On Glosik; a New Sistem ov English Speling* (London, 1870); *English, Dyonisian, and Hellenic Pronunciations of Greek* (ib., 1876); *Logic for Children* (ib., 1882), which consists of two addresses; *Original Nursery Rhymes for Boys and Girls* (1848); *Algebra Identified with Geometry* (1874); *Practical Hints on the Quantitative Pronunciation of Latin* (1874); *Pronunciation for Singers* (1877).

ELLIS, ALSTON (1847-). An American university president, born in Kenton Co., Ky. In 1865 he graduated from Miami University. Between 1867 and 1892 he was principal of schools at Covington and Newport, Ky., and superintendent of schools at Hamilton and Sandusky, Ohio; from 1892 to 1900 he was president of the State Agricultural College of Colorado and during most of this period also director of the Colorado Experiment Station at Fort Collins, Colo.; in 1901 he became president of Ohio University. He served as president of the Ohio Superintendents' Association in 1875, the Ohio Teachers' Association in 1888, the Ohio College Association in 1892-93, and the Ohio Association of Presidents and Deans in 1910-11. Besides many educational reports he is author of a *History of the Ungraded Schools of Ohio*.

ELLIS, EDWARD SYLVESTER (1840-). An American writer, principally known for his boys' stories of adventure. He was born at Geneva, Ohio, and was educated at the New Jersey State Normal School. After teaching for several years, especially at Trenton, N. J., where he was principal of the high school and superintendent of schools, he devoted himself after 1876 exclusively to historical research and literary work. He is author of more than a dozen series of juvenile stories, comprising some 150 volumes, and of such writings as: *The Camp-Fires of General Lee* (1886); *The Indian Wars of the United States* (1892); *History of our Country* (1896); *Dewey and Other Naval Commanders*

(1899); *Low Twelve* (1908); *High Twelve* (1912); *Life of Thomas Jefferson* (1913).

ELLIS, GEORGE EDWARD (1814-94). An American historian and editor. He was born in Boston, graduated at Harvard College in 1833 and at Harvard Divinity School in 1836, spent three years in study and travel in Europe, and from 1840 to 1869, when he resigned, was pastor of the Harvard (Unitarian) Church, Charlestown, Mass. From 1857 to 1863 he was professor of systematic theology in the Harvard Divinity School. In 1864, 1871, and 1879 he was a Lowell Institute lecturer and for a number of years was editor of the *Christian Register* and later of the *Christian Examiner*. He was an overseer of Harvard College in 1850-54 and in 1885 was elected president of the Massachusetts Historical Society. He published: *Sketches of Bunker Hill and Monument* (1843; 4th ed., 1846); *John Mason* (1844); *Anne Hutchinson* (1845); *William Penn* (1847); *Half Century of the Unitarian Controversy* (1857); *The Aims and Purposes of the Founders of Massachusetts and their Treatment of Intruders and Dissentients* (1869); *Memoir of Sir Benjamin Thompson, Count Rumford* (1871); *History of the Battle of Bunker Hill* (1875); *The Red Man and the White Man in North America* (1882); *The Puritan Age and Rule in the Colony of the Massachusetts Bay, 1629-1685* (1888). He wrote chapters for the *Memorial History of Boston* (1881) and for Winsor's *Narrative and Critical History of America* (1886). Consult the memoir by O. B. Frothingham in *Proceedings of the Massachusetts Historical Society* for May, 1895.

ELLIS, SIR HENRY (1777-1869). An English antiquarian, born in London and educated at St. John's College, Oxford. He held a sub librarianship in the Bodleian at Oxford for a few months and was then (1800) appointed to a similar position in the British Museum, where he was chief librarian from 1827 to 1856, when he retired. In 1833 he was knighted by William IV. He edited Brand's *Popular Antiquities* (1813) and several volumes for the Camden Society, published a valuable collection of *Original Letters Illustrative of English History* (11 vols., 1824-46), and wrote an *Introduction to Domesday Book* (2 vols., 1833).

ELLIS, (HENRY) HAVELOCK (1859-). An English criminologist, born at Croydon, Surrey, and educated for a medical career at St. Thomas's Hospital. After teaching for several years in Australia he returned to England in 1880, where he became known as a writer. He wrote: *The Criminal* (1890; 4th ed., 1910); *Man and Woman: A Study of Human Secondary Sexual Characters* (1894; 4th ed., 1904); *A Dialogue in Utopia* (1900); *The World of Dreams* (1911); *The Task of Social Hygiene* (1912); and "Studies in the Psychology of Sex," a series up to 1914, these six volumes: *Sexual Modesty* (1897), *The Evolution of Modesty* (1899; 3d ed., 1910), *Analysis of the Sexual Impulse* (1903; 2d ed., 1913), *Sexual Selection of Man* (1905), *Erotic Symbolism* (1906), and *Sex in Relation to Society* (1910).

ELLIS, JOB BICKNELL (1829-1905). An American botanist, born at Potsdam, N. Y., and educated at Union College. His publications include *North American Fungi*, with B. M. Everhardt (1892), and *North American Fungi* (1878-93). He was an editor of the *Journal of Mycology* from 1885 to 1888.

ELLIS, JOHN VALENTINE (1835–). A Canadian journalist and legislator. He was born in Halifax, Nova Scotia, and was educated there in the public schools. He worked in a printer's office for some years and in 1857 went to St. John, New Brunswick, where he became a reporter. In 1862 he brought out the *St. John Globe*, which he thereafter edited and published. Entering politics in 1882, he sat for five years as the Liberal member for St. John in the New Brunswick Legislature. In 1887–91 he represented St. John in the House of Commons, and in connection with his election there were court proceedings involving him for contempt of court, for which he underwent imprisonment and was sentenced to pay a fine. The outcome of the proceedings increased his popularity, and the fine was paid by public subscription. In 1896–1900 he was again a member of the House of Commons, but in the latter year he was appointed a member of the Dominion Senate. In 1911 he was elected chairman of the Senate Committee on Debates, and also president of the Natural History Society of New Brunswick. He published several political pamphlets.

ELLIS, MINA A. (1875?–). A Canadian explorer and author. She was born at Bewdley, Ontario, and graduated at the Brooklyn (N. Y.) Training School for Nurses. Subsequently she was assistant superintendent of the S. R. Smith Infirmary, Staten Island, and superintendent of the Virginia Hospital, Richmond, Va. In 1901 she married Leonidas Hubbard, a journalist and explorer who perished in Labrador in 1903. After his death she organized an expedition which in 1905 successfully crossed the north-eastern part of the Labrador Peninsula (now the District of Ungava, Province of Quebec) with the object of completing Hubbard's work, and during the journey made many interesting discoveries. She was the first white person to cross the Great Divide between the Naskaupi and George rivers. On returning to the United States she published an account of her journey in *The Bulletin of the American Geographical Society*; also a volume, *A Woman's Way through Unknown Labrador* (1908).

ELLIS, ROBINSON (1834–1913). An English classical scholar, born at Barming. He entered Balliol College, Oxford, and took the degree of B.A. in 1857; became fellow of Trinity College in 1858; received the M.A. degree in 1859; was made professor of Latin in University College, London, 1870; in 1883–93 was University reader in Latin literature, and in 1893 became Corpus professor of Latin literature, Oxford. He edited or wrote: *Catulli Veronensis Liber*, etc. (1878); *Ovid, Ibis* (1881); "Glosses on Apollinaris Sidonius," *Anec. Oxon., Class. Series*, 1, 5 (1885); *Avianus* (1887); *Orientii Carmina*, vol. xvi in the "Corpus Scriptorum Ecclesiasticorum" (1888); *Velleius Paterculus* (1898); *Afina* (1900); *Noctes Manilianae* (1891); *Appendix Vergiliana* (1907), and *The Annalist Licinianus* (1908). He contributed largely to the learned periodicals. He made also a translation of *Catullus* in the metres of the original (1871). His *Commentary on Catullus* (Oxford, 1876; 2d ed., 1889) took rank at once as a masterpiece of erudition and a first-hand study of all the sources of our knowledge of Catullus. For a notice of his work, with a partial list of his writings, consult Gildersleeve in *American Journal of Philology*, vol. xxxiv,

pp. 494–496 (1913). Consult also *The Classical Review*, vol. xxvii, pp. 286–287 (1913).

ELLIS, WILLIAM (1794–1872). An English missionary. He was born in London, Aug. 29, 1794. In 1816 he went to the South Pacific as a missionary of the London Missionary Society. In Tahiti he set up the first printing press in the South Sea Islands. From 1831 to 1841 he was foreign secretary of the London Missionary Society. From 1847 till his death he was pastor of the Congregational church at Hoddesdon, near London. In 1853 Mr. Ellis was sent to Madagascar by the London Missionary Society to investigate the condition and prospects of the Christians in that island. He afterward made two other visits to the island, the last time remaining four years (1861–65). He died at Hoddesdon, June 9, 1872. Mr. Ellis's works include: *Narrative of a Tour through Owhyhee [Hawaii]* (1826); *Polynesian Researches* (1829); *History of Madagascar* (1838), compiled from government papers and reports of missionaries; *Three Visits to Madagascar* (1858); *Madagascar Revisited* (1867); *The Martyr Church [of Madagascar]* (1870). These works are all standard authorities for the countries of which they treat. Consult the *Life* by his son, J. E. Ellis (London, 1873).—**SARAH STICKNEY ELLIS**, Mr. Ellis's second wife, was a voluminous writer and zealous worker in the interests of temperance reform, education, and efforts to improve the condition of young women of the lower classes. For many years she conducted a school for girls (Rawdon House) at Hoddesdon. She wrote: *The Poetry of Life; The Women of England* (1838); *The Young Ladies' Reader* (1845); *Rawdon House* (1848); and many other volumes of like character.

ELLIS, WILLIAM (1828–). An English physicist and astronomer. He was born in Greenwich and in his teens entered the employ of the Royal Observatory, where in 1856–74 he was in charge of the chronometric and electric branch and in 1875–93 of the magnetical and meteorological department. His studies of terrestrial magnetism were particularly important.

ELLIS, WILLIAM HODGSON (1845–). A Canadian physician and chemist. He was born in Bakewell, Derbyshire, England, but came to Canada in his youth and was educated at Toronto University, where he graduated in 1867. In 1866, during the Fenian Raid, he served with the Queen's Own Regiment at Ridgeway. He afterward studied medicine at Toronto University and in Great Britain. Returning to Toronto, he was appointed professor of chemistry in Trinity Medical School and lecturer on chemistry in Trinity University. His next position was that of instructor in chemistry in the Provincial College of Technology. In 1887 he was appointed professor of applied chemistry in the School of Practical Science, Toronto, and in 1900 he became professor of toxicology in Toronto University. He was also given the position of official analyst, inland revenue, Toronto. He was twice elected president of the Canadian Institute, and in 1906 was elected president of the local section of the Chemical Industries Society. He acquired a high reputation as a chemist and analyst.

ELLIS, WILLIAM THOMAS (1873–). An American journalist and author. He was born at Allegheny, Pa., and was educated in the public schools. Until 1894 he served on the

staffs of Philadelphia newspapers, and afterward he was editor of the *International Christian Endeavor* organ (1894-97) and of *Forward* (1897-1902). From 1903 to 1908 he was an editorial writer for the *Philadelphia Press*. In 1906-07 and 1910-11 he made world tours for a newspaper syndicate, investigating social conditions in foreign countries. After 1897 he wrote syndicate Sunday-school lessons, and he also contributed to the *Continent* and other religious magazines. He became known as a frequent lecturer before religious bodies and as one of the founders of the Presbyterian Brotherhood. He is also author of *Men and Missions* (1909) and *Foreign Missions through a Journalist's Eyes*.

ELLIS ISLAND. A small island in the northern part of upper New York Bay, a mile southwest of the Battery (Map: Greater New York, C 6). It was sold by New York State to the United States in 1808, and for many years was used as a powder magazine. In 1891 it was made an immigrant station. The present buildings were erected in 1897, when the original structures were burned.

ELLISON, PRICE (1862-). A Canadian legislator and administrator. He was born and educated in England, but came to Canada in early manhood and took up farming and ranching in British Columbia, becoming the largest wheat grower in that province. He entered politics in 1898 as a Conservative member of the British Columbia Legislature, and in 1909 was appointed Minister of Lands and Works in the Cabinet of Sir Richard McBride (q.v.). In 1910 he became Minister of Finance and Agriculture, and in 1912 a member of the Royal Conservation Commission.

ELLISEN, ELLÉ-SEN, ADOLF (1815-72). A German philologist and literary historian, born at Gartow, and educated at the universities of Göttingen and Paris. From 1849 to 1855 he was a member of the second chamber of the Hanoverian Parliament, of which he became President in 1854. His *Tee- und Asphodelosblüten* (1840), a metrical translation of Chinese and modern Greek poems, is unique. A somewhat similar production entitled *Versuch einer Polyglotte der europäischen Poesie*, vol. i (1846), is a valuable contribution to literary history. His *Analekten der mittel- und neu-griechischen Litteratur* (5 vols., Leipzig, 1855-62) was the most complete work of its kind for many years after its publication. As a translator he was very successful, being principally known for his versions of Montesquieu's *Esprit des Lois* and of Voltaire's selected works (1844-46). His study on *Voltaire als politischer Dichter* is still considered an important contribution.

ELLISTON, ROBERT WILLIAM (1774-1831). A noted English actor. He was born in London, the son of a watchmaker, and was educated at St. Paul's School at the expense of a scholarly uncle. He ran away from home, however, in 1791, and joined a theatrical company at Bath, making his first appearance, in a minor part, in that same year. In 1793 he was highly successful as Romeo. Beginning in 1796, he appeared occasionally in London, at the Haymarket and Covent Garden theatres, while engaged also at Bath and in the management of several playhouses in provincial towns. From 1804 to 1809 he was a member of the Drury Lane Company, but after the theatre was burned opened the

Surrey Theatre, returning to Drury Lane in 1812, where he took leading parts. He became lessee and manager of Drury Lane in 1819, opening it himself as Rover in *Wild Oats*, and later presenting Kean, Macready, and other great actors of his time, but retired a bankrupt in 1826. Subsequently he played at the Surrey Theatre, but his dissipated habits of long standing prevented him from regaining his old prestige, and he died of apoplexy two weeks after his last appearance as Sheva in *The Jew*. Elliston ranked among the great actors of his time, but was even more naturally remarkable as a comedian. He was the author of two plays, *The Venetian Outlaw* and (in collaboration) *No Prelude*, in which he appeared himself. For his life, consult: G. Raymond (London, 1848 and 1857); Oxberry, *Dramatic Biography* (London, 1826); *Actors and Actresses of Great Britain and the United States*, ed. by Matthews and Hutton, vol. ii (New York, 1886).

ELLO'RA. A ruined town in the dominions of the Nizam, not far from the city of Dowlatabad, in lat. 20° 2' N. and long. 75° 13' E. It is celebrated for its wonderful rock-cut temples, of which there are 19 large ones, partly of Brahman and partly of Buddhist origin. The largest is the Brahman Dumnar Lena, cruciform in plan, measuring 150 feet each way. The amalaka, or melon-capitaled columns, of these caves are a noticeable feature. Besides the caves there are monolithic temples hewn bodily out of the rock. The most beautiful is the Brahman temple known as the Kailasa. At its entrance is an antechamber 138 feet wide by 88 deep, with numerous rows of pillars. From this a bridge leads into a great rectangular colonnaded court, 247 feet in length and 150 broad, in the centre of which stands the temple itself, a vast mass of richly carved rock, adorned with four rows of pilasters, with colossal elephants beneath. The interior is about 103 feet long, 56 broad, and 17 high, but the entire exterior forms a pyramid 100 feet high and is overlaid with sculpture. In the great court are numerous ponds, obelisks, colonnades, sphinxes, and on the walls thousands of mythological figures of all kinds, from 10 to 12 feet in height. The antiquity and religious character of the Brahman temples, authorities are not agreed; but at all events they must be subsequent to the epic poems *Ramayana* and *Mahabharata*, because they contain representations taken from these poems. Ferguson assigns the Kailasa to the ninth century; the Buddhist caves are much earlier. Consult Ferguson and Burgess, *The Cave Temples of India* (London, 1880).

ELLS, ROBERT WHEELOCK (1845-1911). A Canadian geologist. He was born in Cornwall, Nova Scotia, and was educated at Acadia University and at McGill, where he graduated in 1872. In the same year he joined the Geological Survey, and he continued in its service for more than 25 years, becoming senior geologist. His reports on the general resources of Nova Scotia, Prince Edward Island, Quebec, and the Northwest Territories were published in the annual volumes of the Geological Survey. He was elected a fellow of the Royal Society of Canada and a fellow of the American Geological Society.

ELLSWORTH. A city, port of entry, and the county seat of Hancock Co., Me., 30 miles

southeast of Bangor, on the Maine Central Railroad (Map: Maine, D 4). It is at the head of navigation on the Union River and has an extensive trade in lumber and shipbuilding interests, also manufactures of lumber, shoes, carriages, sails, and gasoline engines. Abundant water power is supplied by the river, which is spanned by several bridges at this point. The principal public buildings include the courthouse, customhouse, city hall, and a public library. A large United States fish hatchery is located here. Ellsworth was settled in 1763, incorporated in 1800, and chartered as a city in 1869. The government is vested in a mayor and a board of aldermen. The city owns its water works and electric-light plant. Pop., 1900, 4297; 1910, 3549.

ELLSWORTH, EPHRAIM ELMER (1837-61). An American soldier. He was born in Mechanicsville, N. Y., but early removed to Chicago, where he studied law and took charge of a company of cadets which he brought to a fine degree of efficiency and with which he toured the country in the summer of 1860. He became a friend of Abraham Lincoln, whom he persuaded to create a bureau of militia in the War Department. Lincoln gave Ellsworth a lieutenant's commission preliminary to putting him in charge of the militia bureau. He was dangerously sick in the spring of 1861, but in April organized a Zouave regiment (Ellsworth's Zouaves) from among the volunteer firemen of New York and became its colonel. He took part in the first general movement of the Federal forces into Virginia, but at Alexandria, on May 24, was shot dead by a hotel keeper from whose building he had just torn away a Confederate flag. In the North he was regarded as the first martyr to the cause of the Union. He was buried, with imposing military ceremonies, from the White House, in Washington, by special order of President Lincoln.

ELLSWORTH, OLIVER (1745-1807). An American statesman and jurist, born at Windsor, Conn., where his family had been settled since 1665. He studied at Yale and at Princeton, where he graduated in 1766. He studied theology for a year, but gave it up for law. Admitted to the Connecticut bar in 1771, he represented the town of Windsor in the General Assembly of Connecticut from 1773 to 1775 and was soon afterward chosen a member of the Pay Table, a commission having control of expenditure for military purposes during the Revolution. He became State's attorney in 1777 and was a member of the Continental Congress from 1778 to 1783 and was a member of the Council of the Governor of Connecticut (1780-85) and a judge of the State Superior Court (1785-89). In 1787, with Roger Sherman and William Samuel Johnson, he was chosen to represent his State in the Constitutional Convention at Philadelphia, where he distinguished himself by his activity and sound judgment. At the time when disagreement seemed certain on the question of representation, he, with Roger Sherman, proposed what became the basis of the national legislative system. This measure, known as the Connecticut Compromise, provided that the Federal legislature consist of two houses—the upper equally representative of the States, the lower composed of delegations proportioned according to population. On the organization of the

national government, in 1789, he was elected one of the first United States Senators from Connecticut and served in that capacity until 1796. In the Senate he was looked upon as leader of the Administration party and as the personal spokesman of President Washington. Ellsworth's greatest and most lasting service to the United States government was in connection with the establishment of the Federal judiciary. As chairman of the Senate Committee on the Judiciary, he drew up the bill which organized the entire system of Federal courts practically as they exist to-day. As leader of the Federalists in the Senate, he suggested to President Washington the plan of sending John Jay to England in 1794 to negotiate a new treaty with Great Britain; and it was Ellsworth's influence, in the face of violent opposition, that brought about the Senate's approval of the treaty after it had been drawn up. In 1796, by President Washington's appointment, he became Chief Justice of the Supreme Court of the United States, serving until 1799, when President John Adams sent him, with William R. Davie (1756-1820) and William Vans Murry (1726-1803), as commissioner to adjust the numerous disputes between the United States and France. The negotiations, carried on almost entirely by Ellsworth, terminated with the signing of a treaty whereby France conceded a recognition of the rights of neutral vessels, promised the return to citizens of the United States of all ships captured by France, and provided for freedom of commerce between the two countries. After a year in England, during which time, because of failing health, he resigned the chief justiceship (1800), he returned to America. From 1803 until his death he was a member of the Governor's Council in Connecticut, and on the reorganization of the Connecticut judiciary, early in 1807, was appointed Chief Justice of that State, but died before entering upon his duties. Consult W. G. Brown's *Oliver Ellsworth* (New York, 1905) and an excellent brief résumé in F. G. Cook's "Oliver Ellsworth and the Federation," *Atlantic Monthly*, vol. lxxxix, pp. 524-537 (April, 1902).

ELLWANGEN, ɛl'wäng-en. The capital of the Circle of Jagst, Württemberg, Germany, on the Jagst, 55 miles northeast of Stuttgart (Map: Germany, D 4). It is situated amid beautiful valley scenery, on the slope of a hill crowned by the Hohen-Ellwangen Castle. The Romanesque Stifteskirche, dating from 770, is its most interesting building. In the vicinity are the mineral baths of Schrezeim. It has a high school, a gymnasium, and an agricultural school. Its manufactures include leather, envelopes, drumheads, and shafting. It is a busy wool market. Ellwangen was the capital of a Benedictine principality of 140 square miles until 1802. Pop., 1900, 4747; 1910, 4722.

ELLWOOD, CHARLES ABRAM (1873-). An American sociologist, born near Ogdensburg, N. Y. He graduated from Cornell University in 1896 and also studied at the universities of Chicago (Ph.D., 1899) and Berlin. After spending one year at the University of Nebraska as lecturer and instructor he was appointed professor of sociology at the University of Missouri in 1900. He became advisory editor of the *American Journal of Sociology* and associate editor of the *Journal of Criminal Law and Criminology* and was president of the Mis-

souri Confederate Charities in 1904. In addition to monographs and special articles on social psychology, he is author of *Sociology and Modern Social Problems* (1910) and *Sociology in its Psychological Aspects* (1912; Fr. trans., 1914).

ELLWOOD, THOMAS (1639-1714). An English writer, born at Crowell, Oxfordshire. He joined the Quakers, and his zeal for the sect and denunciation of the Established church brought upon him much persecution. He himself was equally intolerant of any division in the Quaker ranks. He was an intimate friend of Milton, and his comment upon reading the manuscript of *Paradise Lost* suggested to the poet the idea of *Paradise Regained*. Ellwood was the author of a number of polemical works, among them *Forgery no Christianity* (1674); two tracts attacking Thomas Hicks the Baptist; *The Foundation of Tithes Shaken* (1678); *Sacred Histories of the Old and New Testaments* (1709); and an *Autobiography* (1714).

ELLWOOD CITY. A borough in Lawrence Co., Pa., 30 miles northwest of Pittsburgh, on the Baltimore and Ohio, the Pittsburgh and Lake Erie, and the Buffalo, Rochester, and Pittsburgh railroads, and on Connoquenessing Creek (Map: Pennsylvania, A 5). It is in a coal-mining district and has large steel-tube mills, steel-car works, building-stone and limestone quarries, foundries and machine shops, iron-works, and manufactories of wire products, metal packings, etc. Pop., 1900, 2243; 1910, 3902.

ELM. A village and health resort in the Canton of Glarus, Switzerland, situated 10 miles southeast of Glarus, in a valley 3000 feet above sea level, surrounded by the high peaks of the Sardon Alps (Map: Switzerland, D 2). On Sept. 11, 1881, the town was buried under an avalanche, which killed 114 people. Pop., 1900, 914; 1910, 908.

ELM (AS., OHG. *elm*, Ger. *Ulm*e, elm, ultimately connected with Lat. *ulmus*, Ir. *leamh*, elm), *Ulmus*. A genus of trees of the family *Urticaceae*, natives of temperate climates. The serrated leaves have unequal sides, and the small flowers which grow in clusters appear before the leaves unfold. One of the most important species is the English elm, *Ulmus campestris*, a tree of 60 to 80 feet in height, with ovate-elliptical, doubly serrated leaves, and almost sessile flowers. The tree is found all over Europe, also in the west of Asia and north of Africa, and introduced into America, and is extensively planted as a street tree. The wood, which is compact and durable, especially in water, is used for a great variety of purposes by wheelwrights, machine makers, ship and boat builders, etc. It is also prized by joiners for its fine grain and the mahogany color which it readily assumes on the application of an acid. It is reckoned superior to the wood of any other species of elm. The bark is used in dyeing and in sugar refining and in times of scarcity has been used in Norway for grinding into meal and mixing in bread, which has a less disagreeable taste than that made from meal mixed with fir bark. The inner bark is used medicinally in cutaneous diseases; it is mucilaginous and has a bitter, astringent taste. The elm balsam (*beaume d'orme*), which was formerly in great repute, is a brownish substance, which is found in dried galls of the elm leaves in the south of Europe, Persia, etc. From these galls in an

earlier stage flows a clear, viscid, sweetish liquid called elm water (*eau d'orme*), which is used for washing wounds, contusions, and sore eyes. The elm is one of the principal timber trees of the British Isles, is most extensively planted, and is a chief ornament of English scenery. The cork-barked elm, a variety of *Ulmus campestris*, is distinguished by the corky wings of the bark of the branches. It is taller than *Ulmus campestris*, of more spreading habit, with much larger leaves, and is a common European tree. The Dutch cork-barked elm is generally considered a variety of *Ulmus campestris*. It has a still more corky bark, still larger leaves, is of very thick growth, but its wood is very inferior. The broad-leaved, or wych, elm (*Ulmus montana*, or *scabra*), a tree of very quick growth, is the only species that can with certainty be regarded as indigenous to Scotland. It has rough broad leaves, a stem less upright than that of the English elm, and large spreading branches. The wood is used for all the purposes of the English elm. Protuberances of gnarled wood are not infrequently produced, which are finely knotted and richly veined; they are much esteemed for veneering and are sometimes very valuable. Varieties of this species are known as the giant elm and Chichester elm. The smooth-leaved elm (*Ulmus glabra*), a native of Europe, is distinguished by much smaller leaves. It is by some regarded as a variety of *Ulmus montana*. Another variety of this species, called the Huntingdon elm, is much esteemed. The Cornish elm (*Ulmus stricta*), now considered a form of *Ulmus campestris*, found in the southwest of England, is remarkable for its rigid, erect, and compact branches. *Ulmus pedunculata*, a continental species with a large spreading head and smooth bark, is distinguished also by the long stalk of its flowers and its ciliated fruit. The American, or white, elm (*Ulmus americana*), which attains its loftiest stature between lat. 42° and 46° N., is a . . . tree, sometimes 120 feet in height. The trunk reaches 60 or 70 feet before it separates into branches, and the widely diffused pendulous branches float gracefully in the air. It is one of the finest street and park trees. In New England it is highly prized for this purpose. There are a number of famous elm trees, among them the Washington elm (q.v.), at Cambridge, Mass., and the old elm on Boston Common. The timber is used for agricultural implements, wagon hubs, saddletrees, and cooperage. The red, or slippery, elm (*Ulmus fulva*) is also common in the basin of the Mississippi as far south as lat. 30° and in western Canada and New England. It attains a height of 50 or 60 feet. The wood is more valuable than that of the white elm, but inferior to the English elm. The leaves and bark yield an abundant mucilage, which is bland and demulcent and esteemed a valuable remedy in catarrh, dysentery, and other complaints. The wahoo, or winged elm (*Ulmus alata*), is a small tree, found from lat. 37° to Florida, Louisiana, and Arkansas, and is remarkable for the branches being furnished on two opposite sides with wings of cork. The wood is fine-grained, compact, and heavy. The cork, or rock, elm (*Ulmus racemosa*), a larger species, attaining a height of 100 feet and a diameter of 3 feet, ranges from western New England to Minnesota and southward. The wood of this species excels in its strength, toughness, flexibility, and durability.

TYPICAL ELM TREES

AMERICAN ELM (showing variable habit of growth in New England).

In China is found a species of elm, the leaves of which bear galls used in tanning and dyeing.

The name "Spanish elm" is given in the West Indies to a tree also called Bois-de-Chypre (*Cordia gerascanthus*), of the family Boraginaceae, the timber of which is valuable; also to *Hamelia ventricosa*, of the family Rubiaceae, the timber of which is known to cabinetmakers as princewood. The water elm (*Planera aquatica*) is a tree 30 to 50 feet high, occurring from North Carolina to Kentucky, Missouri, and southward. The name elm is applied in Australia to two timber trees, *Aphananthe philippinensis* of the family Urticaceae, and *Duboisia myoporoides* of the family Solanaceae. For illustrations, see Plates of DICOTYLEDONS, EDELWEISS, and FLOWERS. See ELM INSECTS.

ELMACIN, ʔVmā-kən (also ELMACINUS, or ELMAKYN), GEORGE (1223-c.74). An Arabian Christian historian, known in the East as Ibn-Amid. He was successively ketib (or secretary) to the court of the sultans of Egypt and (from 1238) secretary to the Council of War. He wrote a history of the Saracens, extending from the time of Mohammed to 1117. The work appeared at Leyden in Arabic and Latin in 1625 and was afterward translated into French as *L'histoire mahométane* (Paris, 1657).

ELMALU, ʔl-māʔlū, or **ALMALEE** (Turkish for "the place of apples"). A town in Asiatic Turkey, in the Vilayet of Konieh, about 45 miles from the coast (Map: Turkey in Asia, A 3). It lies picturesquely surrounded by mountains on all sides except the southwest and has flour mills, tanneries, and a lively trade. Its population is estimated at from 3000 to 4000.

ELMAN, MISCHA (1892-). A distinguished Russian violinist, born at Talnoje. He showed such precocious and remarkable talent that when he was six years old his father took him to Odessa, where he studied four years with Fidelmann, a pupil of Brodsky. In 1902 Leopold Auer (q.v.) heard him and was so much impressed that he prevailed upon the Czar to suspend the rule barring pupils of the Jewish faith from the Imperial Conservatory of St. Petersburg. Here Elman continued his studies for two years under Auer with such success that at his début in 1904 he was unanimously acclaimed as a violinist of the first rank. His subsequent tours of Germany were a succession of triumphs. He visited the United States in 1908 and proved such an attraction that he was heard again with unabated enthusiasm in 1911, 1912, 1913, and 1914. His talent for the violin amounts to positive genius. His tone is large and powerful, his technic stupendous and unerring, his conception and interpretation those of the mature artist.

EL MEKHEIR, or **EL MESHERIF**. See BÉRBER.

ELMENDORF, THERESA HUBBELL (WEST) (1855-). An American librarian, born at Pardeeville, Wis. She graduated from Miss Wheelock's Seminary, Milwaukee, Wis., in 1874. In 1896 she married Henry Livingston Elmdorf (died 1906). From 1880 to 1896 she was deputy librarian and librarian of the Milwaukee Public Library and after 1906 vice librarian of the Buffalo Public Library. She was president of the New York Library Association in 1903-04 and of the American Library Association in 1911-12—the first woman to hold that office. She served as editor of the *American Library*

Association Catalogue and published several articles in library periodicals.

ELMES, ʔlmz, HARVEY LONSDALE (1813-47). An English architect, born at Chichester, the son of James Elmes (1782-1862), a well-known architect and author of his time. In 1836 he was successful among 86 in competition for the design of St. George's Hall, Liverpool. He was likewise successful in a subsequent competition for the design of the assize courts in the same city, and when it was decided to include the hall and the courts in one building he prepared a new design. The work of construction, begun in 1841, was superintended by Elmes until ill health obliged him to withdraw in 1847, when he was succeeded by C. R. Cockerell. The Collegiate Institution at Liverpool and a county asylum at West Derby were also his work.

ELMET. A small principality in ancient Britain, between Leeds and York, "roughly represented by the West Riding of Yorkshire." It retained its independence until early in the seventh century. Edwin (q.v.), King of Deira, on conquering the kingdoms of Bernicia and Elmet, established the Kingdom of Northumbria by the union of Deira, Bernicia, and Elmet. Consult Green, *The Making of England* (London, 1882).

ELMINA, ʔl-mē'nā (native name *Dena*). A fortified seaport of the British Colony of the Gold Coast, West Africa, situated 8 miles west of Cape Coast Castle. The castle is the residence of the government officials of the district. It is the chief outlet for the trade of Ashanti. Elmina became the chief exporting point on the Gold Coast during the Dutch occupation, but it has greatly declined since then and suffered much during the Ashanti wars. It came under English control in 1872, when it was claimed by the King of Ashanti, the result being the Ashanti wars of 1873-74. Pop., 1901, 3973.

ELM INSECTS. The elm seems peculiarly susceptible to the attacks of foliage-eating insects. Most of these, however, are foreign species, which have been accidentally imported and acclimated and which are likely to attack the

ELM-LEAF BEETLE (*Galeruca xanthomelana*).

a, Adult beetle; b, full-grown larva; c, elm leaf, with grubs eating and laying eggs; d, eggs (magnified).

European elm in preference to American species. Hence it has been recommended that a few European elms be included within all plantations to serve as traps for the insects, which may thus be attacked more easily than if scattered over

the whole plantation. The gypsy moth, brown-tail (see MOTH, BROWN-TAILED), tussock moth (q.v.), and other defoliators, are more or less numerous, especially in New England, where great sums of money (see GYPSY MOTH) have been and continually are spent by local governments in suppression of the evil; while the bagworm and various minor insects, such as bark lice and leaf beetles, attack these trees in the South and West.

The *Elm-Leaf Beetle* is, of all these, perhaps the most generally destructive to the foliage of this tree. It is a well-known European pest, which first appeared in the United States about 1837 and has gradually become widespread. It is a yellowish-brown chrysomelid beetle, a quarter of an inch long, with three indistinct dark stripes on the wings. The beetles begin to feed while the leaves are growing and eat round holes in them. They soon deposit clusters of bottle-shaped orange-colored eggs on the under sides of the leaves and then die. The caterpillar-like grubs speedily hatch and begin feeding. They are black at first, but become more yellowish with each molt, until finally they are wholly yellow except three dark stripes. South of Philadelphia two broods are usually produced annually, but northward only one. The larvæ feed voraciously and soon skeletonize the leaves, and the infested tree rapidly becomes as if burned. The grubs then crawl or fall to the ground and go into the pupa state near or on the surface of the soil, sometimes so numerously as to make a noticeable yellow carpet all about the trunk of the tree. Ordinarily, however, they are more scattered, seeking crevices which will protect them somewhat; and in this state those of the single northern brood or of the second southern brood pass the winter. Full details of this life history will be found in Marlatt's *Elm Leaf Beetle*, published as "Circular No. 8" by the Department of Agriculture (Washington, 1895), and the author recommends the following remedial measures: "The adults, for a week or two after emerging, feed on the newly expanded foliage, and a spraying with Paris green or other arsenical will destroy the great majority of them. Especial pains should be taken to accomplish the destruction of the insect in this stage. . . . If rains interfere with spraying for the adults, or if it be neglected, the trees should be sprayed with arsenical promptly on the first appearance of the larvæ, and the application perhaps renewed a week or 10 days later, especially if rains have intervened."

ELMIRA. A village in Waterloo Co., Ontario, Canada, situated on the Canadian Pacific and Grand Trunk railways, 12 miles north of Berlin (Map: Ontario, D 6). The manufacturing industries include foundries and machine shops, boot factories, manufactories of transmission supplies, saw and planing mills, a brickyard, and grain elevators. The village owns its electric-light plant and water works, and is supplied with hydroelectric power. Pop., 1901, 1060; 1911, 1782.

ELMIRA. A city and the county seat of Chemung Co., N. Y., 147 miles southeast of Buffalo, on the Lackawanna, the Erie, the Northern Central (Pennsylvania System), and the Lehigh Valley railroads, and on the Chemung River (Map: New York, D 6). It has the New York State Reformatory (see **ELMIRA REFORMATORY**), a State armory, Elmira Free Academy, Elmira College (q.v.), a United States Govern-

ment building (. . . post office and Federal court . . . Library, Arnot-Ogden Memorial Hospital, Arnot Art Gallery, and homes for orphans and the aged. A monument to the Rev. Thomas K. Beecher is one of the features of the city. Eldridge, Hoffman, Wisner, and Riverside parks and Roricks Glen are worthy of mention. Elmira is noted for the extent and variety of its manufactures, the chief industrial plants being railroad-car shops, iron and steel bridge works, steel-plate works, valve and radiator works, manufactories of boots and shoes, automobile parts, tables, bicycles, glass, fire engines, tobacco and cigars, boilers and engines, doors, sashes and blinds, etc., hardwood-finishing works, silk and knitting mills, tobacco warehouses, dye works, breweries and aluminium works. The city government is administered under the charter of 1906 by a mayor, chosen every two years, and a unicameral city council. Besides the executive and aldermen there are elected by the people the recorder, city judge, and 12 supervisors. Near the site of Elmira, now marked by a monument to General Sullivan, was fought, on Aug. 29, 1779, the battle of Newtown, in which General Sullivan with an American army of 5000 defeated a force of Indians and Tories led by Sir John Johnson and Joseph Brant and numbering about 1500. First permanently settled in 1788, and incorporated as the village of Newtown in 1815, then reincorporated as the village of Elmira in 1828, Elmira became the county seat in 1836 and was chartered as a city in 1864. In 1861 it was chosen as the State military rendezvous and in 1864-65 had one of the northern prisons in which Confederate prisoners were confined. Pop., 1900, 35,672; 1910, 37,176; 1914, (est.), 37,816.

ELMIRA COLLEGE. An institution for the higher education of women, founded in Elmira, N. Y., in 1855. It was the first institution exclusively for women which had at the time of its founding as high a standing as colleges for men. It is nonsectarian, but was founded under Presbyterian control. The college confers the degrees of B.A., B.Sc., and M.Sc. upon students of classical and scientific courses, and B.M. upon students of music. There is a graduate department and a summer session. The attendance in 1912-13 was 240, and the faculty numbered 18. The productive funds amount to about \$130,000 and the annual income to about \$90,000. The library contains about 11,000 volumes. The president in 1914 was Rev. A. C. MacKenzie, D.D.

ELMIRA HEIGHTS. A village in Chemung Co., N. Y., adjoining Elmira, on the Erie, the Delaware, Lackawanna, and Western, and the Lehigh Valley railroads. It has bridge works, machine shops, knitting mills, and table and pump factories. Pop., 1900, 1763; 1910, 2732.

ELMIRA REFORMATORY. An institution situated in Elmira, N. Y. It is the State reformatory for males between the ages of 16 and 30 who have not been previously committed to a State prison. Regarding the term of imprisonment the law states: "Every sentence . . . shall be a general sentence to imprisonment in the New York State Reformatory at Elmira, and the courts of this State . . . imposing such sentence shall not fix or limit the duration thereof. The term of such imprisonment . . . shall be terminated by the managers

of the reformatory, . . . but such imprisonment shall not exceed the maximum term provided by law for the crime for which the prisoner was convicted and sentenced." (Laws of 1877, sec. 2, c. 173.) The institution was opened in 1876, though the law authorizing it was enacted in 1866. Its establishment introduced a new era in prison science. It has had great success and has been widely copied. In comprehensiveness and adaptation of training to individual needs it is unequalled. Down to September, 1910, it had cared for 20,604 prisoners. The average number of prisoners for the year ending Sept. 30, 1910, was 1266, and the average daily maintenance cost per inmate was \$0.535. Consult: Winter, *The Elmira Reformatory* (New York, 1891); Wines, *Punishment and Reformation* (ib., 1895); Brockway, *Fifty Years of Prison Service* (ib., 1912); and the Yearbooks of the Reformatory. See BROCKWAY, Z. R.; PENOLOGY; REFORMATORIES.

ELMO'S FIRE, SAINT (from St. Elmo, St. Peter Gonzales, 1190-1246, a Spanish Dominican who is invoked by sailors on the Mediterranean during storms). The popular name of an appearance sometimes seen, especially in southern climates, during thunderstorms, of a brush or star of light at the tops of masts, spires, or other pointed objects. It is sometimes accompanied by a hissing noise and is of the same nature as the light caused by electricity streaming off from points connected with an electrical machine. The phenomenon, as seen at sea, was woven by the Greeks into the myth of Castor and Pollux; and even yet such lights at the masthead are considered by sailors a sign that they are to fear from the storm.

ELMSHORN, *ëlms'hörn*. A town in the Prussian Province of Schleswig-Holstein, 24 miles northwest of Hamburg, situated on the navigable Krückau (Map: Prussia, C 2). It manufactures cloth and leather goods, boots and shoes, hats, mineral waters, and soaps. There are also iron foundries, dyeing establishments, and shipbuilding works, and it has a large shipping trade by river. Pop., 1900, 13,640; 1910, 14,789.

ELMSLEY, *ëlms'li*, PETER (1773-1825). An English classical scholar. He was educated at Westminster School and at Christ Church, Oxford, and in 1823 was made principal of St. Alban Hall, Oxford, and Camden professor of ancient history at the university. He visited Italy in search of classical manuscripts and, after devoting the winter of 1818 to researches at the Laurentian Library in Florence, assisted Sir Humphry Davy in deciphering the papyri found in Herculaneum (1819). He is remembered chiefly for his critical edition of the *Heracleida*, the *Medea*, and the *Bacchæ* of Euripides, (q.v.) and of the *Œdipus Tyrannus* and *Œdipus Coloneus* of Sophocles (q.v.). He first recognized that the Laurentian manuscript of Sophocles was supreme among manuscripts of that author. Consult *Elmsleiana Critica* (Cambridge, 1833) and Sandys, *A History of Classical Scholarship*, vol. iii (ib., 1908).

ELMWOOD PLACE. A village in Hamilton Co., Ohio, adjoining Cincinnati, on the Cincinnati, Hamilton, and Dayton and the Cleveland, Cincinnati, Chicago, and St. Louis railroads, and on the Miami and Erie Canal. It contains freight yards and extensive steel plants. The village has persistently refused annexation to Cincinnati. Pop., 1900, 2582; 1910, 3423.

EL OBEID, *ël-ô-bād'*, or **IL OBEID**. The capital of Kordofan, a province of the Egyptian Sudan, 2300 feet above sea level, in lat. 12° 20' N. and long. 31° E. (Map: Africa, G 3). It consists of a number of villages inhabited by distinct races. There are a number of mosques and an old Catholic church. Pop. (est.), 8000 (largely of Arabs and Nubians). It has a growing trade in gum, feathers, ostrich products, and ivory. Near El Obeid an Anglo-Egyptian army under Hicks Pasha was annihilated by a Mahdist force, Nov. 3-5, 1883.

ELOBEY (*ä'lo-bä'ë*) **ISLANDS**. Two small islands belonging to Spain, situated off the Guinea coast, Africa, in Corisco Bay, at the mouth of the Muni River, in lat. 0° 57' N., long. 9° 30' E. Elobey Grande, the larger, is of much less importance than Elobey Chico, where several factories have been established, the first dating from 1872. Both islands are flat, the smaller being well wooded. There is a Spanish missionary school on Elobey Chico. Pop., 1900, 331; 1910, 354.

ELUCUTION (Lat. *elocutio*, from *eloqui*, to speak out, from *e*, out + *loqui*, to speak). The art of effective speaking, more especially of public speaking. It regards solely the utterance or delivery; while the wider art of oratory, of which elocution is a branch, takes account also of the matter spoken. See **READING**.

ELOHIM, *ël-ô-hēm'* (Heb. gods, pl. of *'eloah*, Ar. *'ilahu*, Aramaic *'elah*, Ass. *ilu*, god). The plural of *Eloah*, used when more than one god is intended, but also in the sense of "deity" in general and as a designation of the one god worshipped by Israel. In the latter . . . attachment of the plural ending serves, as it often does in the Semitic languages, to express the idea of greatness, supremacy, and the like. Elohim is therefore equivalent to "the great *Eloah*," the *Eloah* par excellence. Already in the Tell el-Amarna tablets (beginning of the fourteenth century B.C.), we find, in letters addressed by Palestinian officials to the Egyptian King, *ilani*, the plural of *ilu*, 'god,' used . . . with *ilu*, as *Elohim* with *El* or *Eloah* in some parts of the Old Testament. The use of Elohim in Genesis, more extensive originally than the present Masoretic text would lead us to believe, as a critical study of the early versions reveals, is regarded by some scholars as indicating an original polytheistic setting, while others think that Elohim was preferred to *Yahwe* in the Kingdom of Israel. In view of the numerous Israelitish names compounded with *Yahu* or *Yo*, and the frequent occurrence of *Yaw* or *Yo* on the wine jars found at Samaria (see **AHAB**; **SAMARIA**), the latter view seems less plausible. It may reasonably be supposed that in later times Elohim was preferred from a desire to avoid the stronger anthropomorphic implications connected with *Yahwe*, which is more of a personal name. In this way the substitution of "Elohim" in Ps. liii for "Yahwe" in Ps. xiv may be explained. The same feeling may also have had something to do with the disappearance of *Yahwe* from ordinary use and the various attempts to disguise it. See **JEHOVAH**; **YAHWE**; **PENTATEUCH**.

ELOHIST AND YAHWIST. Terms adopted by certain modern biblical scholars to denote the authors of two literary works which they believe to have been used as historical sources in the composition of the Pentateuch as we have it and to have been embodied in it. The terms

are purely conventional names assigned because the one source is supposed to be characterized by the use of *Elohim* (q.v.); the other by the use of *Yahwe* (q.v.). See PENTATEUCH.

ELOI. See ELIGIUS.

ELOISE, ɛl'ô-êz. A hospital settlement in Wayne Co., Mich., 16 miles from Detroit, on the Michigan Central Railroad. It contains a large hospital, an infirmary, and a sanatorium. The institutions are under the control of the Wayne County Superintendents of the Poor, a board established in 1832. The property is worth about \$900,000. Pop., 1914 (local est.), 1750.

ELON COLLEGE. A coeducational institution of higher learning, founded under the auspices of the Christian church, at Elon College, N. C., in 1890. It succeeded the Graham Normal College, founded in 1865. The campus consists of 25 acres, covered for the most part with native oak and hickory. The buildings include the Administration Building, the first college building to be erected, the West Dormitory, the East Dormitory, the power plant, the Alumni Building, the Ladies' Hall, Music, Art, and Expression studios, Domestic Science kitchen, gymnasium, and college dining hall. The students in the college in 1914 numbered 386, of whom 332 were undergraduates. The instructors numbered 22. The endowment amounted to \$150,000, and the income from all sources to about \$75,000. The plant of the college was valued at \$300,000. The library contains about 12,000 volumes. The president in 1914 was William Allen Harper, M.A., Litt.D., LL.D.

ELONGATION (ML. *elongatio*, from Lat. *elongare*, to lengthen, from *e*, out + *longus*, long; connected with Goth. *laggs*, Icel. *langr*, OHG., Ger. *lang*, AS. *lang*, long, Eng. *long*), **ANGLE OF.** The difference between the geocentric longitudes (q.v.) of a planet and the sun. The close circumpolar stars (such as Polaris) are sometimes said to be in elongation when their azimuth (q.v.) measured from the north point of the horizon has its greatest possible value.

ELOPEMENT (from *elope*, from Dutch *ontloopen*, to run away, from *ont*, away + *loopen*. Eng. *lope*, to run). In law, the act of a married woman who abandons her husband and cohabits with another man. In the early period of English law, before the right of divorce was recognized, it was provided by the Statute of Westminster II (13 Edw. I, c. 34) that an eloping wife, if condemned by the church and unforgiven by her husband, should lose her dower in her husband's lands. To-day the consequences of the act is to free the husband from his common-law liability for her support and in all countries where divorce is recognized to entitle the husband to a dissolution of the marriage relation. Where the elopement is notorious, the husband is not bound to pay debts of her contracting, and whoever, with notice of the separation, gives her credit does so at his own risk. See ADULTERY; DIVORCE; HUSBAND AND WIFE.

EL-ORDEH, ɛl-ôr-dâ', Arabic for "the rest house," also known as NEW DONGOLA. The capital of the Province of Dongola, in the Egyptian Sudan, situated on the left bank of the Nile. It is a prosperous town, with a number of public buildings and fine bazars. It has a population of about 20,000. Seventy-five miles above El-Ordeh, on the right bank of the Nile, lies Old Dongola, or Dongola Aguza, once a flourish-

ing place, now reduced to an insignificant sand-swept village.

ELOTHERIUM (Neo-Lat., from Gk. *ἑλος*, *helos*, marsh + *θηρίον*, *thêrion*, wild beast). A large fossil pig of the Miocene rocks of Europe and North America, and differing from the other Miocene members of the family in the reduction of the number of toes on both hind and fore feet to two. See SWINE.

ELOYSIUS, SAINT. See ELIGIUS.

EL PASO, ɛl pã'sô. A city, port of entry, and the county seat of El Paso Co., Tex., directly opposite Juarez, Mexico, on the Rio Grande (Map: Texas, A 6). It is of great commercial importance as a gateway of the trade between Mexico and the United States and also as a railroad centre, being the terminus of the National of Mexico, the El Paso and Southwestern, the Texas and Pacific, the Southern Pacific, the Galveston, Harrisburg, and San Antonio, and the Rio Grande and El Paso railroads. El Paso is situated at an altitude of 3762 feet and is popular as a health resort. Noteworthy features include the State School of Mines, Fort Bliss (a regimental cavalry post), Carnegie library, Knights of Columbus Home, 13 public parks, Federal building, Masonic temple, courthouse, city hall, several fine hotels, and Clouderoft, which is in the vicinity. The city carries on an extensive trade in copper, silver, and lead, machinery, live stock, wool, and hides, and has important wholesale and jobbing interests. Its port handled in 1912 merchandise valued at \$10,852,000, of which \$6,172,000 represented exports. El Paso is also the centre of a rich fruit and vegetable growing region, the great Elephant Butte Dam, erected at a cost of nearly \$10,000,000, furnishing ample water for irrigation. The industrial establishments include a large custom smelter, a wood-finishing and box factory, foundries and machine shops, cement plant, large railroad repair shops, brick and tile works, sash and door, macaroni, and cigar factories, brass works, and flour mills. El Paso was incorporated as a city in 1873 and adopted the commission form of government in 1907. Its receipts in 1912 were \$1,986,000, while its payments amounted to \$1,882,000; the chief items of expenditure being: education, \$164,000; police department, \$54,000; and fire department, \$65,000. The water-works system, costing \$1,500,000, is owned by the city. El Paso is supposed to have been visited early by Spanish explorers. During the Civil War it was occupied alternately by Federal and Confederate troops and for a time was the base for operations against New Mexico and Arizona. Long an unimportant village, with a population in 1880 of only 736, it developed rapidly. Pop., 1890, 10,338; 1900, 15,906; 1910 (including suburbs), 39,279; 1914 (U. S. est.), 49,505.

EL PASO DEL NORTE, ɛl-pã'sô ðɛl nôr'tá. See CIUDAD JUAREZ.

ELPHINSTONE, GEORGE KEITH. See KEITH, GEORGE KEITH-ELPHINSTONE.

ELPHINSTONE, MOUNTSTUART (1779-1859). An Anglo-Indian statesman and historian, one of the founders of the Indian Empire, the fourth son of John, eleventh Baron Elphinstone. Part of his boyhood was spent in Edinburgh Castle, of which stronghold his father was governor. He was educated at the Edinburgh High School and afterward at Kensington. In his seventeenth year he proceeded to Calcutta in the employ of the East India Company and two years

later, in 1798, escaped the massacre of Europeans at Benares only by the fleetness of his horse. He became assistant to the British Resident at Poonah in 1801 and later, although a civilian, acted as aid-de-camp to Sir Arthur Wellesley and took an active part in the battles of Assaye, Argaum, and Gavilghat. After the Mahratta War he was appointed Resident at Nagpur. In 1808 he was sent as envoy to Kabul and in 1811 was made Resident at Poonah. On the renewal of hostilities with the Mahrattas in 1817 he assumed command of the English troops during the battle of Kirki and contributed largely to their success. He subsequently governed the conquered districts with remarkable force and consideration, preserving the native customs and rights, so as to win the regard of his subjects and strengthen British rule. In 1819-27 he was Lieutenant Governor of Bombay and drew up the Elphinstone Code of laws which laid the foundation of state education in India. He spent two years in travel, visiting Egypt, Palestine, Greece, Turkey, Italy, and France, and returned to England in 1829, after 33 years' absence. He was twice offered the governor-generalship of India, but declined, and his last 30 years were devoted to study and authorship. He wrote *An Account of the Kingdom of Cabul and its Dependencies in Tartary, Persia, and India* (1815) and a *History of India* (1841). Both are standard authorities. He died Nov. 20, 1859. A statue in his honor was erected in St. Paul's Cathedral. Consult Colebrooke, *Life of Mountstuart Elphinstone* (London, 1884), and Cotton, *Mountstuart Elphinstone and the Making of South-Western India* (Oxford, 1896).

ELPHINSTONE, WILLIAM (c.1431-1514). A Scottish prelate and statesman, founder of Aberdeen University. The natural son of William Elphinstone, rector of Kirkmichael, and Archdeacon of Teviotdale, he was born at Glasgow and educated there at the grammar school and University. In his twenty-ninth year he became a student of civil and canon law at the University of Paris, where in three years he obtained a doctorate of decrees, was appointed professor, and also became lecturer at Orleans University. He returned to Scotland after an absence of nine years and became successively official general of the diocese of Glasgow (1471-72), rector of the university (1474), and Archdeacon of Lismore, judicial official of Lothian, and Privy Councilor (1478). He effectively accomplished several important and delicate missions to France, England, Burgundy, and Austria, and his services were rewarded with the bishopric of Ross in 1481 and that of Aberdeen in 1483. In the last year of the reign of James III he was Chancellor of the kingdom. Under James IV he discharged important diplomatic missions to England and the Continent, and was Keeper of the Privy Seal from 1492 until his death. The establishment of printing in Scotland was due to his influence and support. In 1494 he procured the papal bull for the foundation of Aberdeen University, which was dedicated to St. Mary in 1500, and its name afterward changed to King's College. His principal work is *Breviarium Aberdonense* (1508-10; reprint, 2 vols., London, 1850).

EL RENO. A city and the county seat of Canadian Co., Okla., 27 miles west of Oklahoma City, on the Rock Island, and the St. Louis. El Reno and Western railroads, and on the North

Fork of the Canadian River (Map: Oklahoma, D 3). It has a Carnegie library, a sanitarium, Indian schools, Sacred Heart Academy, and a United States land office. Its industries include cotton gins, machine shops, brick plant, flour and alfalfa mills, and manufacturing of brooms, cement stone, and washing machines. There are also repair shops and division offices of the Rock Island system. El Reno has adopted the commission form of government and owns its water works. Pop., 1900, 3383; 1910, 7872.

EL ROSARIO, ɛl rô-sá-ré-ô. See ROSARIO.

ELSASS and **ELSASS-LOTHRINGEN**, ɛl'ss-ɛl'ss-lô'thîng-en. See ALSACE-LORRAINE.

ELSBERG, ɛl'sbêrk, LOUIS (1836-85). An American physician, born at Gerlohn, Prussia. He emigrated to America with his parents in 1849 and settled in Philadelphia, where he attended the public schools. Later he attended Jefferson Medical College. He published numerous papers on throat diseases, introduced laryngo-copy into the United States, and wrote *The Throat and the Production of the Voice* (1880) and *Harmony, Sound, and Music*. He first illustrated the character of undertones and the division of sound and invented many instruments which are used in operations on the throat and ear. From 1880 to 1884 he published the *Archives of Laryngology*.

ELSHEIMER, ɛl'shî-mêr, ADAM (1578-1620). A German landscape and historical painter and etcher. He was born in Frankfort-on-the-Main and studied there under Uffenbach and probably in Venice under Rottenhammer. In 1600 he went to Rome, where he obtained the patronage of Pope Paul V, and resided until his death. He is chiefly remarkable for the influence he exercised over all schools of painting, especially the Dutch. He introduced a more realistic and natural spirit into the biblical and mythological genre and perfected landscape painting on a small scale. His pictures are simple and unpretentious in conception and motive as well as size. He shows great feeling for idyllic beauty and for form and excels in depicting the nude. His color is rich in richness and depth, and his treatment of light is both natural and artificial, is not so pronounced as Rembrandt, but in his solution of atmospheric problems rather resembles Rubens. He is well represented in the Dresden Gallery by "The Flight into Egypt," "Philemon and Baucis," and other pictures; in the Munich Pinakothek, by "St. John the Baptist Preaching" and others; in the Louvre, by the "Good Samaritan"; in Madrid, by the "Mocking of Ceres"; and there are also pictures by him in the galleries of Berlin, Vienna, Frankfort, Florence, Rome, and other cities. Consult Bode, *Studien zur Geschichte der holländischen Malerei* (Brunswick, 1883).

ELSIE VENNER, A ROMANCE OF DESTINY. A novel by Oliver Wendell Holmes, published in 2 vols. in 1861.

ELSINORE, ɛl'sî-nôr', Dan. **HELSINGÖR**, hêl'sîng-êr. A seaport of Denmark, on the island of Zealand, situated on the west shore of the sound, at its narrowest part, opposite the Swedish town of Helsingborg, and 24 miles north of Copenhagen (Map: Denmark, F 2). The town has a charming site, with several interesting buildings, notably the town hall and the hospital. To the north is the castle of Kronborg, built by Frederick II of Denmark in

1577-85, to insure the collection of tolls from vessels passing through the strait, the toll being exacted till 1857. This imposing castle, now used as barracks, is associated with Shakespeare's *Hamlet*. The platform before the castle, where the ghost appears in the play, is shown the visitor, as is also Hamlet's so-called tomb—a column on a hill not far away. Marienlyst, formerly a summer residence of the royal family, now a bathing place, lies three-quarters of a mile to the northwest. Elsinore's industries consist chiefly of cloth weaving, net making, shipbuilding, founding, and general marine engineering. The harbor is excellent, admitting ships of 20-feet draught, and is frequented by numerous vessels, especially for repairs. Coal is the principal article of import. Pop., 1901, 13,902; 1911, 13,783.

ELSON, HENRY WILLIAM (1857-). An American historian, born in [unclear] Co., Ohio. He graduated from Thiel College (Pa.) in 1886, from the Lutheran Theological Seminary (Philadelphia) in 1889, and studied also at the University of Pennsylvania. After serving as pastor at [unclear] (1889-93), and of St. Stephen's, [unclear] (1893-95), he left the ministry to lecture for the University Extension Society of Philadelphia. In 1905 he became professor of history and economics at Ohio University. He is author of several excellent text and reference books: *Side Lights on American History* (2 vols., 1899-1900); *How to Teach History* (1901); *Star-Gazers' Hand-Book* (1902; 2d ed., 1909); *History of the United States of America* (1904; 2d ed., 1908); *Elson's History* (5 vols., 1905); *School History of the United States* (1906); *A Child's Guide to American History* (1909); *Comets* (1910); *Guide to English History* (1911); *Guide to German History* (1912).

ELSON, LOUIS CHARLES (1848-). An American writer on music, born in Boston, Mass. After studying music in Boston and Leipzig, he returned to Boston, where he became editor of the *Vox Humana*. Afterward he wrote for the *Musical Herald* and the *Boston Courier* and became musical editor of the *Boston Advertiser*. After 1881 he was lecturer at the New England Conservatory of Music. He translated and arranged many songs. His first literary success was *Curiosities of Music* (1883). Among his other books are: *German Songs and Song Writers* (1884); *The Great Composers* (1897); *Our National Music* (1899), a standard work; *Shakespeare in Music* (1900); *History of American Music* (1904); *Folksongs of Many Nations* (1905); *Musical Dictionary* (1906); *Mistakes and Disputed Points in Music* (1910). He wrote the articles on music for the *New Standard Encyclopædia* and for the *Americana*, and was editor in chief of *Modern Music and Musicians* (1912).

ELSSLER, FANNY (1810-84). An Austrian dancer, born in Vienna. Along with her elder sister, Therese, she was trained for the ballet in Vienna and Naples. The first triumph of the sisters took place in Berlin, where they appeared in 1830. In her subsequent travels, by her beauty, amiability, and mastery of her art, Fanny charmed all classes of society. In 1841 the two sisters went to America, where they excited unwonted enthusiasm. After Fanny had earned laurels in St. Petersburg she returned, in 1851, to Vienna, to take a final leave of the stage. She then retired to Hamburg, where she

remained till, in 1854, she settled finally in Vienna.—**THERESE** (1808-78) was less graceful than her sister, but also exhibited great strength, boldness, and agility. In 1850 she became the wife of Prince Adalbert of Prussia (who died in 1873) and was made Baroness von Barnim by the King of Prussia.

ELSTER. The name of two rivers of Germany, more exactly known as the White and the Black Elster (Map: Germany, E 3). The former, rising at the foot of the Elster Mountains, on the northwest boundary of Bohemia, flows north as far as Leipzig, where it turns westward and empties into the Saale (q.v.), 3 miles south of Halle, in Prussian Saxony, after a course of nearly 120 miles. Its chief affluent, the Pleisse, joins it near Leipzig. It has been made navigable for small vessels as far as Leipzig, not far from which point the river divides, the left branch, known as the Luppe, also flowing into the Saale. The Black Elster rises in the Kingdom of Saxony, within 2 miles of Elstra, flows north into Prussia, then bends northwest and joins the Elbe 8 miles southeast of Wittenberg. Its total length is about 135 miles, of which only about 40 miles have been made navigable.

ELSTRACKE, REGINALD, or RENOLD (c.1590-1630). An English line engraver. He is usually considered to have been born in London, but more probably came originally from Flanders. He studied under Crispin van de Passe in Cologne and came to London with the younger members of his master's family in the early part of the seventeenth century. He worked chiefly for booksellers and executed his plates entirely with the graver. The prints of his portraits are very scarce. His works express a good deal of character in a firm and forcible manner, but are of more interest historically than as works of art. His chief work was a volume of 32 plates, *Basiliologia; a Book of Kings, being the true and lively effigies of all our English Kings from the Conquest untill this present* (1618). Among his most prized engravings is the double whole-length portrait of Mary Stuart, Queen of Scots, and Lord Darnley, a print of which was purchased in 1884 by the British Museum for £150. Other rare portraits are Princess Elizabeth, James I. Anne of Denmark, and Sir Richard Whittington, with his hand resting on a skull.

ELTON (Tatar *Altan-Nor*, Gold Lake). A salt lake in the Russian Government of Astrakhan, situated about 70 miles east of the Volga (Map: Russia, G 5). The lake with an area of 62 square miles is the remnant of a much larger body of water which has become partly desiccated, and now its surface is about 50 feet below sea level. It is very shallow, and its bottom is covered with salt. It receives eight salt-water streams, but has no visible outlet. Salt began to be extracted from the lake as early as 1655. In 1747 the government began to work the salt deposits of Elton, and the output up to 1862 amounted to over 8,000,000 tons. With the opening of the Crimean salt fields and the construction of the railway to the salt lake Bakuntchak, the working of the Elton salt deposits was given up (1862).

ELTON, CHARLES ISAAC (1839-1900). An English lawyer, born at Southampton and educated at Balliol College and at Trinity College, Oxford. He was elected justice of the peace for Somerset and was member of Parliament for

West Somerset from 1884 to 1885 and from 1885 to 1892. His principal works include: *Commons and Waste Lands* (1868); *Copyholds and Customary Tenures* (2d ed., 1893); *Custom and Tenant Right* (1882); *Origins of English History* (1890); *W. Shakespeare: His Family and Friends* (1904).

ELTON, JAMES FREDERIC (1840-77). An English explorer. He entered the Bengal army at the time of the Indian mutiny and saw much service in that colony as well as in China, becoming captain. Subsequently he was attached to the staff of the French army in Mexico, in 1866, and published an account of his adventures there, entitled *With the French in Mexico* (1867). In 1868 he went to Natal and began a series of explorations through Africa, the results of which were reported by him in his journal illustrated by himself with exceptionally fine maps and sketches. These journals were edited by H. B. Cotterill, under the title *Travels and Researches among the Lakes and Mountains of Eastern and Central Africa* (1879). He entered the government service in 1873 and was appointed British Consul in Portuguese Territory, with residence at Mozambique, in 1875. While returning from a successful mission to the chiefs of several African tribes, he was stricken with fever, from which he died in Ugogo, on Dec. 13, 1877, near the town of Usekhe. He wrote a book entitled *Notes and Sketches in East Africa and on the Suppression of the Slave-Trade, 1873-1877*, which was not published for some years.

ELTON, OLIVER (1861-). An English literary historian, educated at Westminster School and at Corpus Christi, Oxford. He was lecturer on English literature at Owens College, Manchester, in 1890-1900, and then became professor at the University of Liverpool. With F. Y. Powell he published for the Folklore Society a version of the first nine books of Saxo Grammaticus's *Historia Danica* (1894), and he edited the *Life of Frederick York Powell* (1906). Besides contributions to reviews and to the *Encyclopædia Britannica*, he wrote: *The Augustan Ages* (1899); the standard study of Michael Drayton (1906); *Modern Studies* (1907); *Survey of English Literature from 1780 to 1830* (1912).

ELTZBACHER, ELTSBÄG-ER, PAUL (1868-). A German jurist. Educated at Heidelberg, Leipzig, Strasbourg, and Göttingen, he became a judge and then privatdozent at Halle and in 1906 professor of law at the Berlin Handelshochschule. He wrote: *Ueber Rechtsbegriffe* (1900); *Die Handlungsfähigkeit* (1903); *Die Unterlassungsklage* (1906); *Grossberliner Mietsverträge* (1913), etc.; but is best known by his *Anarchismus* (1900; Eng. trans. by Byington, 1908), which has been translated into nearly every modern language and is the most complete and unbiased treatment of the subject. In 1910 he wrote on anarchism for the *Handbuch der Politik*.

ELUTRIATION (from Lat. *elutriare*, to wash out, from *eluvare*, to wash out, from *e*, out + *luere*, to wash). The process of separating fine and coarse pulverized materials by putting them in suspension in water and taking advantage of the different rates of sedimentation for the various materials. Thus, coarse, heavy substances will sink to the bottom of a vessel quickly, leaving finer material behind. The process may be repeated by successive decant-

ings or siphonings of the liquid. The process is used for preparing high-grade clays for porcelain manufacture. In this treatment the clay is first disintegrated in water, after which the mixture passes through a long series of connected troughs of very low pitch, in which the sandy particles settle out. The clay suspended in water is then led to settling tanks, where the clay slowly sinks to the bottom and is drawn off into filter presses. (Consult Ries, *Clays, Occurrence, Properties, and Uses* (New York, 1908, and Watts, *Bureau of Mines, Bull.* 53, 1913.) Elutriation on a grand scale is exhibited by nature in the deposit of fine earths. The immense beds of sedimentary clay, covering many square miles in area, are the result of the slow subsidence of fine particles suspended in water passing in a slow but steady current in estuaries and discharging into lakes or ocean where the sediment settles.

ELVAS, ALVASH. A fortified city of Portugal, situated in a very fruitful district in the eastern part of the Province of Alemtejo, 10 miles west of the Spanish town of Badajoz (Map: Portugal, B 3). It is the strongest fortress in Portugal, having two formidable forts, Fort Santa Lucia and Fort Rippe (also known as Nossa Senhora da Graça)—the former to the south and the latter, almost entirely shell proof, to the north, of the city. Elvas has a cathedral, built at the close of the fifteenth century, which contains some fine paintings; there are also a theatre, a hospital, and a fine aqueduct, begun in the fifteenth century and completed in 1622. This aqueduct consists of four tiers of arches, built upon one another, rising to the height of about 120 feet. In the surrounding districts olives and grapes are cultivated, and some iron is mined. Elvas has been the seat of a bishop since 1570. The chief manufactures are arms and jewelry. Pop., 1890, 13,291; 1900, 14,018. Elvas is the Roman Alpesa and the Moorish Balesh. It was fortified by the Moors and later became an object of contention between the Moors, Portuguese, and Spaniards, until the Portuguese finally won it in 1226. During the Peninsular War it was a place of great strategic importance and in 1808 was captured by the French under Marshal Junot. It was soon afterward given up, in accordance with the terms of the Convention of Cintra.

ELVENICH, EL'VE-NIK, PETER JOSEPH (1796-1886). A German theologian and philosopher. He was born at Embken, District of Aix-la-Chapelle, and was educated at Münster and Bonn. He was appointed professor at Bonn in 1826 and three years later was called to the chair of philosophy at Breslau, where in 1840 he also became royal librarian. He was one of the foremost defenders of Hermesianism, and after the publication of the papal decree of Jan. 7, 1836, denouncing the writings of Hermes, he visited Rome in order to secure a revocation of the edict. His principal works include: *Acta Hermesiana* (2d ed., 1837); *Aktenstücke zur geheimen Geschichte des Hermesianismus* (1845); *Die Wesenheit des menschlichen Geistes* (1857).

ELVER. See EEL.

ELWART, EL'VÄR, ANTOINE AIMABLE ELIE (1808-77). A French musician. He was born in Paris, where he first appeared in early boyhood as a chorister at Saint-Eustache. After completing his studies under Reicha, Fétis, and Le Sueur, at the Conservatory, where in 1828

he had founded the since celebrated *concerts d'émulation*, he went to Italy in 1834 as the recipient of the Prix de Rome. Upon his return in 1836 he was appointed professor at the Conservatory and retained this position for more than 30 years. His writings on music include: *Dupré, sa vie artistique* (1838); *Le chanteur accompagnateur* (1844); *Histoire de la société des concerts du conservatoire* (2d ed., 1863; continued up to 1885 by Deldevez); *Histoire des concerts populaires* (1864).

ELWELL, FRANK EDWIN (1858–). An American sculptor. He was born at Concord, Mass., where he received his first instruction under May Alcott and Daniel Chester French. His real training was derived at the Ecole des Beaux-Arts and the Academy of Ghent and under Falguière in Paris. In 1885 he returned to America and opened a studio in New York. Elwell possesses striking originality of conception and fertility of invention. His execution is variable, and occasionally deficient in line, but his work is always essentially sculptural. It includes such creations as "Death and Strength" (Edam, Holland); "Diana and the Lion" (Art Institute, Chicago); "Egypt Awakening" (Paris Salon, 1896); an equestrian statue of General Hancock at Gettysburg; "New Life" (1899, Lowell Cemetery, Mass.); "Kronos" (Harvard University); a monument to Edwin Booth at the statue of "Dickens and Little Nell" in Park, Philadelphia; a monument to General di Cesnola in Kensico Cemetery, N. Y. (1903); marble statues representing Greece and Rome for the New York City customhouse; busts of Vice Presidents Morton and Hobart (Senate Chamber, Washington); statues of Rear Admiral Davis (1910, Naval Monument, Vicksburg) and General Steele (Military Park, Vicksburg, 1911). His "Water Boy of Pompeii" is in the Metropolitan Museum (New York City), where he was curator of statuary from 1902 to 1905. He received a highest award at the World's Fair, Chicago, 1893, and became in 1910 director of the New York School of Applied Design for Women.

ELWOOD. A city in Madison Co., Ind., about 40 miles (direct) north-northeast of Indianapolis, on the Lake Erie and Western and the Pittsburgh, Cincinnati, Chicago, and St. Louis railroads (Map: Indiana, F 4). It is in the natural-gas belt, carries on a trade in live stock, grain, and produce, and has large tinplate mills, ironworks, saw and planing mills, brickyards, canning factories, and manufactures of plate glass, lamp chimneys, shovels, etc. The city maintains a public library. Pop., 1900, 12,950; 1910, 11,028.

ELY, ELY. A city of Cambridgeshire, England, situated on rising ground near the Ouse, on the Isle of Ely, in the fen country, 16 miles north-northeast of Cambridge (Map: England, G 4). The city consists of a single long street, retaining several mediæval dwelling houses. It derives its celebrity from its ecclesiastical architecture: the ancient churches of St. Mary and of the Holy Trinity, the Episcopal Palace of the fifteenth and sixteenth centuries, remains of conventual establishments, and, above all, the cathedral, one of the largest in England, begun in 1083, completed in 1534, and restored since 1847. It presents an interesting mixture of Saxon, Norman, and early English architectural types. The interior dimensions are:

length, 530 feet; breadth, 77 feet; height, 62 feet; length of transepts, 180 feet. Its principal features are the decorated octagon and lantern tower, 170 feet high, built between 1322 and 1342, and the only Gothic dome extant; the late Norman nave; the English Galilee, or Western, porch; the decorated lady chapel; and the choir, with its fine carvings and sculptures. Extensive market gardening is carried on in the neighborhood of Ely for the metropolitan and Cambridge markets, and the manufacture of pottery and pipes engages the attention of a few of the inhabitants. Etheldreda, daughter of Anna, King of East Anglia, founded a monastery here about 673 A.D. In 870 the Danes ravaged the Isle of Ely and destroyed the monastery, which was rebuilt in 970 by St. Ethelwold, Bishop of Winchester. This remained till 1083, when the new church was begun, which was converted into the cathedral and the abbey erected into a see in 1109. Ely was one of the last strongholds of the Saxons after the Conquest, and was the "camp of refuge" of Hereward in 1071. Among the celebrities connected with Ely are Abbot Thurston, who, with Hereward, defended the Isle against William the Conqueror; Longchamps, Chancellor and Regent under Richard I; and Bishop Andrews. Pop., 1901, 7700; 1911, 7917. Consult: Stewart, *Architectural History of Ely Cathedral* (London, 1868); Murray, *Eastern Cathedrals* (ib., 1881); Sweeting, *The Cathedral Church of Ely* (ib., 1901); Curtis, "Ely Cathedral," in *The Architectural Review*, vol. ii, N. S. (Boston, 1913).

ELY. A city and summer resort in St. Louis Co., Minn., 117 miles north by east of Duluth, on the Duluth and Iron Range Railroad (Map: Minnesota, F 3). It is situated in the centre of the Vermilion Iron range, near a number of lakes and waterfalls; has a fine high-school building and city hall and carries on a trade in iron, lumber, fish, and furs. Under a revised charter of 1903 its government is vested in a mayor, elected annually, and a board of aldermen. The city owns its water works and electric-light plant. Pop., 1900, 3717; 1910, 3572.

ELY, ISLE OF. A marshy plain comprising the southern part of the Bedford Level and the part of Cambridgeshire, England, north of the Ouse (Map: England, G 4).

ELY, RICHARD THEODORE (1854–). An American economist, born at Ripley, N. Y. He graduated at Columbia College in 1876, received the degree of Ph.D. at Heidelberg in 1879, and was head of the department of political economy at Johns Hopkins University from 1881 to 1892, when he became professor of political economy in the University of Wisconsin. He was secretary of the American Economic Association from its inception in 1885 to 1892 and president from 1899 to 1902. In 1894 an unsuccessful attempt was made to depose him from his chair at Wisconsin for teaching Socialistic doctrines. He was one of the first of the professional economists to break with the notion that government interference in economic affairs is always an evil, and in his writings he frequently advocates state interference as a means of regulation. His publications include: *French and German Socialism* (1883); *Labor Movement in America* (1886); *Taxation in American States and Cities* (1888); *Political Economy* (1889); *Outlines of Economics*

(1893); *Socialism: An Examination of its Nature, its Strength, and its Weakness, with Suggestions for Social Reform* (1894); *The Social Law of Service; Monopolies and Trusts* (1900; new ed., 1912); *The Coming City* (1902); *Studies in the Evolution of Industrial Society* (1903; new ed., 1913). In collaboration with Prof. G. R. Wicker he wrote *Elementary Principles of Economics* (1907); and in collaboration with T. S. Adams, M. O. Lorenz, and A. A. Young, *Outlines of Economics* (1908; several subsequent editions). In 1914 he published *Property and Contract in their Relation to the Distribution of Wealth*. He also edited *Macmillan's Citizen's Library of Economics, Politics, and Sociology*. Throughout his teaching career he was a frequent contributor to periodical literature, both scientific and popular.

ELY, THEODORE NEWEL (1846–). An American civil engineer. He was born at Watertown, N. Y., and graduated from Rensselaer Polytechnic Institute in 1866. He also received the honorary degrees of M.A. from Yale University in 1897 and Sc.D. from Hamilton College in 1904. From 1868 to 1910 he was connected with the engineering department of the Pennsylvania Railroad, for the last 17 years of this period being chief of the motive-power department of lines west of Erie and Pittsburgh. He held directorships in the Pennsylvania Steel Company and the Cambria Steel Company, was trustee of the Drexel Institute and the Philadelphia Commercial Museum, and director of the Pennsylvania Academy of Fine Arts. In 1904 he became president of the Eastern Railroad Association, and he was chosen an honorary member of the American Institute of Architects and vice president of the American Academy in Rome.

ELYMAS (Lat., from Gk. Ἐλύμας). A Jewish sorcerer and prophet, who, according to Acts xiii. 6-12, opposed Paul before the Proconsul Sergius Paulus at Paphos in Cyprus and was smitten with temporary blindness. There are two difficulties connected with his personality—one concerning his name, the other his historical character. In verse 6 he is called Bar Jesus, in verse 8 Elymas, which is there explained as meaning "Magian," or sorcerer. Some scholars think Bar Jesus was the original name and explain Elymas by an Arabic root as "The Wise Man." Others prefer Elymas, and regard Bar Jesus as a Christian name designating him after the passing of his blindness and his consequent conversion as a "follower of Jesus." In the latter case Elymas should probably be understood as a contraction of Elymaios, "the Elamite," which might have been interpreted vaguely as "A wise man from the East," or "Magian," and originally have been a proper name, Elam. (See **ELAM**.) The close similarity of this story to that of Simon Magus in Acts viii has led many to see in it a defense of Paul against the identification of this Apostle with the Magian so common among Judaizing Christians. Yet it seems possible that, as in the case of Simon, so in this instance, an actual historic personage has been seized upon, first by the opponents of Paul as the basis of a caricature, and then by his friends to set forth his equality with those accounted preeminent both in confutation of error and in miraculous deed. The historical Elam-Elymas may, like Simon of Gitta, have been a Gnostic thinker and a student of occult science.

Consult Krenkel, *Josephus und Lukas* (Leipzig, 1894).

ELYOT, or ELIOT, SIR THOMAS (c.1490-1546). An English diplomat and author, born probably in Wiltshire. He was twice Ambassador to Charles V (1531 and 1536) and was a member of Parliament in 1542. In 1531 he published a volume on the ethics of government, *The Boke named the Governour*, of which there is an excellent edition by H. H. S. Croft (1880); it is based on a work by Francesco Patrizzi. Elyot was a friend of Thomas More and Thomas Cromwell. He translated from the Greek and the Italian, wrote a popular work on medicine, *The Castell of Helth* (1534), and compiled the first elaborate Latin-English dictionary, entitled *The Dictionary of Syr T. Eliot, knyght* (London, 1538 and 1545), which was the basis of Cooper's *Thesaurus*. Consult Croft's preface to his edition of the *Governour*.

ELYRIA, è-lîr'î-à. A city and the county seat of Lorain Co., Ohio, on the Black River, 25 miles west of Cleveland, 7 miles south of Lake Erie, and on the Lake Shore and Michigan Southern, and the Baltimore and Ohio railroads (Map: Ohio, F 3). It has a public library, a hospital, and a fine natural park. The city has extensive manufactures, including automobiles, telephones, home-lighting plants, flour, feed, canned goods, concrete blocks and moldings, paints, metal polish, switchboards, screws, machine parts, iron, steel, iron strip steel, etc. Elyria is the source of Berea sandstone. The water works are owned by the city. Pop., 1900, 8791; 1910, 14,825; 1914 (U. S. est.), 17,396.

ÉLYSÉE, è-lé'zà', PALAIS DE L'. The official residence of the President of the French Republic, on the Rue du Faubourg Saint-Honoré and the Champs Élysées, Paris, built by Molet in 1718. It was originally the mansion of the Comte d'Evreux, but, under Louis XV, the residence of Madame de Pompadour. It was occupied by Louis Napoleon while President in 1848-52 and has served its present purpose since 1871.

ELYSIAN (è-lîzh'ân) FIELDS (Lat. *Elysii Campi*). A term used in general for Elysium (q.v.) and particularly applied to a region near Baiæ, Italy, supposed, from its beauty and fertility, to resemble the Abodes of the Blessed. See **ISLANDS OF THE BLESSED**.

ELYSII CAMPI. See **ELYSIAN FIELDS**.

ELYSIUM, è-lîzh'î-ûm (Lat., from Gk. Ἐλύσιον (Πεδίον), *Elysion (Pedion)*, Elysian, Plain). In classical mythology, the place where the souls of the good dwell after death. Two conceptions are clearly marked. The earlier is indicated in the *Odyssey* (iv, 563 ff.) and continues till late times. Here Elysium is a place at the end of the world, by the ocean, to which specially favored mortals are transported by the gods, usually without separation of the soul from the body, to enjoy perpetual blessedness. Elysium is thus identified with the Islands of the Blessed (q.v.), or is said to be situated on these islands. The other view, less ancient and perhaps less common, is prominent in Vergil (*Æneid*, vi, 541 ff.), where Elysium is that part of the Lower World in which dwell the souls or shades of the good (cf. **TARTARUS**). This view differs from the first conception, not merely in the location of Elysium, but in making it a

place to which access is determined by the deeds done in this life and not by the favor of the gods. In Homer Elysium is promised to Menelaus solely because he is the husband of Helen and son-in-law of Zeus. Elysium is not to be confused with the asphodel meadow in Homer, where the shades of the dead lead a mournful, restless life in the gloomy realm of Hades. Consult Rohde, *Psyche* (2d ed., Heidelberg, 1896).

ELZE, ɛl'tse, KARL (1821-89). A German literary historian. He was born in Dessau and was educated at Leipzig and Berlin. After frequent travels in England and Scotland, where he was engaged in extensive literary researches, he was in 1875 appointed to the newly established chair of English language and literature at the University of Halle. Like Michael Bernays and other contemporaneous investigators, he sought to apply the methods of classical philology to the modern science and devoted himself chiefly to the classics of English literature. One of his best and most popular works was the *Englischer Liederschatz*, which passed through five editions (5th ed., 1869). Other important works include: the biographical and critical study entitled *William Shakespeare* (1876; trans. by Schmitz, 1888); the biography of Lord Byron (1870); the biography of Sir Walter Scott (1864); *Grundriss der englischen Philologie* (1877).

ELZEVIR. A family of Dutch printers, famous for their editions of the classics and of French historical and political authors, among their best-known series being *Les petites républiques*.—**LOUIS** (1540-1617), who founded the family's reputation, began printing in 1583, and on his own account in 1592 in Leyden with Merula's *Eutropius*.—Of his seven sons five followed his profession: **MATTHIEU** in 1617-1622, **LOUIS** in 1590-1621, **GILLES** in 1599, **JOOST** about 1617, and **BONAVENTURE** in 1617-1652. The last, in partnership with various nephews, was the most celebrated.—A grandnephew, **JEAN**, continued the business in Leyden.—**DANIEL**, a son of Bonaventure, with **LOUIS**, the third of his name, established a house in Amsterdam (1655), where the latter had been printing since 1638.—Other less noted Elzevirs were **ISAAC**, who managed the house at Leyden (1617-25), **PETER**, grandson of **JOOST**, at Utrecht (1667-75), and **ABRAHAM**, university printer at Leyden (1681-1712). They printed in all about 1618 books—1097 in Latin, 48 in Greek, 356 in French, 43 in Flemish, 18 in German, 27 in Italian, and 29 in Oriental languages. The Elzevir books are distinguished less by the critical preparation of their texts than by the elegance of the types and the choice grade of the paper. All the more important Elzevirs, in particular editions of the classics, are highly valued by collectors. Consult A. Willems, *Les Elzevier: histoire et annales typographiques* (Bruxelles, 1880).

EMANA'TION (Lat. *emanatio*, a flowing forth, from *emanare*, to flow forth, from *e.* out + *manare*, to drip). In theology and philosophy, the name of an ancient doctrine which considered the world of finite spirit and of matter as being an involuntary outpouring from the Divine Essence. What thus flows forth from original perfection was regarded as gradually degenerating, and this was thought to account for the origin of evil. It is interesting to notice how emanation regards the starting point of development as superior to its goal, while the prevailing tendency of evolutionism

is to reverse these values and consider developmental movement as a progress. The idea of emanation came from the East and pervaded the Neoplatonic philosophy of Alexandria (see NEOPLATONISM) and Gnosticism (q.v.), while there are hints and possibly even the germ of it in Indian philosophy and Zoroastrianism (q.v.).

EMAN'CIPATION (Lat. *emancipatio*, from *emancipare*, to manumit, from *e*, out + *mancipare*, to deliver over, from *manus*, hand + *capere*, to take). In Roman law, the liberation of a person from paternal authority (*patria potestas*) by the act of the *paterfamilias*. Paternal authority over a son was regularly extinguished only by death. Paternal authority over a daughter ended when the daughter passed, by marriage, under the hand (*manus*), i.e., into the power of a husband; but this was not regarded as an emancipation in the full sense of the term. Emancipation not only liberated the son or daughter from all parental control, but had the further effect of cutting him or her off from the rights as well as the responsibilities of the filial relation. In the oldest Roman law no such liberation was possible. The Roman father had, however, the power of selling his child as *mancipium*; and the status of a child thus sold was technically that of a slave, but practically, by ancient custom, that of a domestic servant bound out for a term of years. An ancient rule, ascribed to Romulus and repeated in the Twelve Tables, declared that a son sold three times should be free from his father. Taking advantage of this rule, the Roman lawyers devised a form of voluntary liberation. The son was sold three times in succession to a friend of the family, who, after the first and second sales respectively, set him free by manumission, just as a slave was set free, and after the third sale, by which the paternal authority was broken, sold him back to the father. The father, who at that stage of the transaction held the son, not as a son, but as a *mancipium*, then emancipated him by manumission. As the law of the Twelve Tables mentioned the son only, and not the daughter, and as this law came to be regarded as regulating emancipation rather than as furnishing the legal basis for emancipation, it was held that a daughter might be emancipated after a single sale. This form of liberating the son or daughter existed till the time of Justinian, who abolished it entirely, substituting a declaration of emancipation by the father before a magistrate.

The emancipation of a son who was married and had children did not take these children out of the grandfather's power. On the other hand, grandchildren could be emancipated, although their father remained in his father's power. Emancipation took the person emancipated not only out of the household, but out of the agnatic family, and thus deprived him of all kindred in the legal sense and of all rights of inheritance. As far as inheritance from the father was concerned, the law was changed in the last century of the Republic by edict of the prætors, who admitted the emancipated son to share in his father's estate on condition that his own estate was "collated," i.e., reckoned in as a part of the paternal estate. As far as rights of inheritance from collaterals were concerned, the emancipated person was at a disadvantage until Justinian changed the entire law of succession, and made *cognatio*, or kinship by blood, decisive.

Teutonic law never recognized a lifelong authority of the head of the house over his children; not only did the daughter pass out of the father's control by marriage, but the son became free from the father as soon as he set up a home of his own. This mode of emancipation was described in the Middle Ages as "Saxon emancipation" (*emancipatio Saxonica*). In modern civil law the liberation of a person from paternal authority, as from the authority of a guardian, comes with the attainment of full age; and the term "emancipation" is applied to the case where a person receives some or all of the rights of full age before attaining full age. Thus, the French law declares that sons as well as daughters are emancipated by marriage, and further provides for the emancipation of a minor with the consent of his parents at 15, and with the consent of the family council, if neither of his parents is living, at 18. Similar provisions are to be found in other European codes.

The freeing of a slave was not termed at Roman law emancipation, but manumission. See MANUMISSION; FAMILY; PATRIA POTESTAS; SLAVERY.

EMANCIPATION, PROCLAMATION OF. The document issued by Abraham Lincoln, as commander in chief of the armies of the United States, Jan. 1, 1863, declaring slavery abolished by military authority in all the South except Tennessee and the parts of Louisiana and Virginia then held by Union arms. For a long time President Lincoln had resisted the appeals of the radical Republicans for such a proclamation. He waited until he thought public opinion was ready for it and until he had achieved a victory and not seem the victor of a defeated combatant. After McClellan's unsuccessful campaign against Richmond he felt that the emancipation of the slaves was a moral and a military necessity for its effect upon both South and North. Antietam furnished the victory he awaited, and on Sept. 22, 1862, a preliminary proclamation was issued, decreeing the emancipation on Jan. 1, 1863, of all slaves in the States which should till then continue in a state of rebellion. In this he also stated that thenceforth, as before, the restoration of the Union should be the object of the prosecution of the war. The act, of course, carried no other authority than that which the President exercised as commander in chief of the military forces of the government. The final proclamation, in view of its purposes and effects, must ever hold an important place in American history.

BY THE PRESIDENT OF THE UNITED STATES OF AMERICA.

A PROCLAMATION.

Whereas, on the 22d of September, in the year of our Lord one thousand eight hundred sixty-two, a proclamation was issued by the President of the United States, containing, among other things, the following, to wit:

"That on the 1st day of January, in the year of our Lord one thousand eight hundred sixty-three, all persons held as slaves within any State, or designated part of a State, the people whereof shall then be in rebellion against the United States, shall be then, thenceforward, and forever free; and the executive Government of the United States, including the military and naval authority thereof, will recognize and main-

tain the freedom of such persons, and will do no act or acts to repress such persons, or any of them, in any efforts they may make for their actual freedom.

"That the Executive will, on the first day of January, aforesaid, by proclamation, designate the States and parts of States, if any, in which the people thereof respectively shall then be in rebellion against the United States; and the fact that any State, or the people thereof, shall on that day be in good faith represented in the Congress of the United States by members chosen thereto at elections wherein a majority of the qualified voters of such State shall have participated, shall, in the absence of strong countervailing testimony, be deemed conclusive evidence that such State and the people thereof are not then in rebellion against the United States."

Now, therefore, I, Abraham Lincoln, President of the United States, by virtue of the power in me vested as commander in chief of the army and navy of the United States and as a fit and necessary war measure for repressing said rebellion, do, on this first day of January, in the year of our Lord one thousand eight hundred sixty-three, and in accordance with my purpose so to do, publicly proclaimed for the full period of 100 days from the day first above mentioned, order and designate as the States and parts of States wherein the people thereof, respectively, are this day in rebellion against the United States, the following, to wit:

Arkansas, Texas, Louisiana (except the parishes of Saint Bernard, Plaquemines, Jefferson, Saint John, Saint Charles, Saint James, Ascension, Assumption, Terre Bonne, Lafourche, Saint Mary, Saint Martin, and Orleans, including the city of New Orleans), Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia (except the forty-eight counties designated as West Virginia, and also the counties of Berkeley, Accomac, Northampton, Elizabeth City, York, Princess Ann, and Norfolk, including the cities of Norfolk and Portsmouth), and which excepted parts are, for the present, left precisely as if this proclamation were not issued.

And by virtue of the power and for the purpose aforesaid, I do order and declare that all persons held as slaves within said designated States and parts of States are, and henceforward shall be, free; and that the Executive Government of the United States, including the military and naval authorities thereof, will recognize and maintain the freedom of said persons.

And I hereby enjoin upon the people so declared to be free, to abstain from all violence, unless in necessary self-defense; and I recommend to them that in all cases, when allowed, they labor faithfully for reasonable wages.

And I further declare and make known that such persons of suitable condition will be received into the armed service of the United States to garrison forts, positions, stations, and other places, and to man vessels of all sorts in said service.

And upon this act, sincerely believed to be an act of justice, warranted by the Constitution, upon military necessity, I invoke the considerate judgment of mankind and the gracious favor of Almighty God.

In witness whereof, I have hereunto set my

hand, and caused the seal of the United States to be affixed.

Done at the city of Washington, this first day of January, in the year of our Lord [L.S.] one thousand eight hundred sixty-three, and of the independence of the United States of America the 'thirtieth'.

By the President: ABRAHAM LINCOLN.

WILLIAM H. SEWARD, Secretary of State.

The effect of the proclamation on the legal status of the slaves gave rise to some discussion, but a solution of that problem became unnecessary, inasmuch as the work of emancipation in the United States was completed by the adoption of Article XIII of the amendments to the Constitution; and the reconstruction of the States in insurrection proceeded upon that basis. Consult Whiting, *War Powers of the President* (Boston, 1862). See SLAVERY; RECONSTRUCTION.

EMANIUM. See ACTINIUM.

EMANTS, ém'ants, MARCELLUS (1848-). A Dutch writer. He was born in Voorburg, near The Hague, and studied at Leyden. He traveled extensively and from 1872 to 1880 was associated as editor with several publications. His experiences in Sweden, southern Europe, and Africa are recorded in the following works: *Op Reis door Zweden* (1877); *Monaco* (1878); *Langs den Nyl* (1884); *Uit Spanje* (1886). He is also known for his epics, which include *Lilith*, a poem in three cantos (1889); for *Godenscherming* (1883); for several dramas, among which is *Adolf van Gelder* (1887); and for his novels, among which is *Een nagelaten Beken-tenis* (1895).

EMANUEL. See EMMANUEL.

EMAUS, ém'â-ûs. A borough in Lehigh Co., Pa., 6 miles southwest of Allentown, on the Philadelphia and Reading and the Perkiomen railroads (Map: Pennsylvania, L 6). It contains ironworks, furnaces, silk mills, a brick plant, a cigar and a shirt factory. The city owns its water works. Settled about 1723, Emaus soon became the seat of a Moravian church, and in 1761 was laid out as a congregational village (Gemein Ort), receiving its name from the sainted Bishop in 1859. Schools were established here in 1734, but on account of attacks by the Indians were forced to move to Bethlehem (q.v.). These schools now comprise the Moravian College at that city. Pop., 1900, 1468; 1910, 3501.

EMBA, ém'bâ. A river in the Russian Central Asiatic Territory of Uralsk, rising in the Mugojar Mountains. It flows in a south-westerly direction and enters the Caspian Sea by a wide estuary, after a course of 350 miles. It is partly dry during the summer season and is unnavigable. Fish abound. The principal tributary is the Temir.

EMBALMING (from Gk. βάλαμον, *bal-samon*, balsam, balm). The art of preserving bodies after death. The art has attained to great perfection by the ancient Egyptians, who regarded the preservation of the dead as a religious duty. Not only human beings, but also cats, ibises, ichneumons, and other sacred animals were regularly embalmed. In 1880 the mummy of King Mer-en-rê, who lived about 25 centuries before our era, was found in his pyramid at Saqqara, and its excellent state of preservation attests the efficacy of the methods of embalming used at that remote period. From time to time various improvements in the art

seem to have been introduced, and under the New Empire the processes employed were highly elaborate. At the same time certain innovations appeared: the heart was removed and replaced by a stone scarabæus, and the viscera were placed in four jars, each of which was under the protection of one of the four sons of Osiris. (See CANOPIC VASES.) Both Herodotus and Diodorus describe the methods of embalming practiced in their day by the Egyptians. According to Herodotus (c.450 B.C.), three methods were in vogue. The most expensive of these was as follows: The brain was removed through the nostrils, partly by the use of a curved metal instrument and partly by the injection of certain drugs. The intestines were withdrawn through an opening in the left flank, and the abdominal cavity, after being washed out with palm wine, was filled with myrrh, cassia, and other aromatic substances. The opening was then sewed up, and the body was steeped for 70 days in a strong solution of natron, which seems to have been a mixture of common salt, saltpetre, and sodium sulphate. After this the body was washed, elaborately bandaged in linen strips smeared with resins, and was finally placed in the coffin. This method of embalming was within the reach of the wealthy only. A second and cheaper method consisted in injecting into the abdominal cavity cedar oil (*κεδρα*, *cedria*), or turpentine, and steeping the body for 70 days in a solution of caustic soda. The contents of the abdomen, broken down by the injection, were then allowed to escape, and the body was ready for burial. By the third method the abdomen was washed out with *syrmace*, and the body was pickled in caustic soda for 70 days. Diodorus also speaks (towards the close of the first century B.C.) of three modes of embalming practiced by the Egyptians. The first method cost, he says, a silver talent (about \$1200), the second 20 minas (about \$400), while the third cost but "a trifle." His account agrees in the main with that of Herodotus, though he gives some additional details. According to Diodorus, a scissor first drew with a reed pen a line down the left flank of the body, and following this line the *paraschistes*, or 'cutter,' made a deep incision. The embalmers then withdrew the entrails through this incision and proceeded to embalm the body. From an examination in modern times of many Egyptian mummies, it is evident that the methods described by the classical writers were not the only ones employed. Some mummies have been merely dried in the sand; others have been treated with caustic soda or boiled in resins and bitumen, with or without the flank incision, having the brain removed through the eyes or base of the cranium, with the viscera returned into the body, placed upon it, or deposited in jars in shapes of the genii of the dead, the skin partially gilded, the flank incision covered with a tin plate, the fingers cased in silver, the eyes removed and replaced. The mummies are generally wrapped in linen bandages and placed in costly coffins. Embalming was practiced to some extent by the early Christians in Egypt, their views in regard to the resurrection being doubtless influenced by Egyptian ideas. The Guanches, or ancient inhabitants of the Canary Isles, used an elaborate process like that of the Egyptians; and desiccated bodies, preserved for centuries by atmospheric or other agencies, have been found in France, Sicily, England,

and America, especially in Central America and Peru.

Modern Embalming. The art of embalming was probably never lost in Europe. The development of modern methods, however, may be said to date from the beginning of the eighteenth century. It is said that arterial injection of embalming fluid for the preservation of a dead body was first practiced successfully by Dr. Frederick Ruysch, of Amsterdam (1665-1717), who also treated the internal organs with alcohol, after removing and cleansing them, replacing them finally. His secret of preservation of color and form died with him. Following him in the work of embalming came Dr. William Hunter (q.v.), the celebrated anatomist, who employed as an arterial injection a solution containing oil of turpentine, Venice turpentine, oil of lavender, oil of rosemary, and vermilion. He also removed the abdominal and thoracic organs, cleaned and injected them, soaked them in camphorated spirits of wine, and then returned them to their cavities, packed in a powder composed of camphor, resin, and nitre. This powder he also placed in all external orifices. The body was then anointed with oil of rosemary and oil of lavender and placed upon a layer of dry plaster that its moisture might be extracted from it. Bodies embalmed after this method by William Hunter or his brother, John Hunter (q.v.), in perfect condition, are deposited in the museum of the Royal College of Surgeons, London. Other physicians, chief among them being Drs. Matthew Baillie, Sheldon, and Joshua Brooks, used similar methods. Jean Nicolas Gannal (1791-1852), a French chemist, employed a solution with which he wet the body and which he injected into the carotid artery; the solution was composed of acetate of lead and sulphate of alumina, together with some form of arsenic. His son, a physician of Paris, used a similar solution, but without the arsenic and with the addition of certain essential oils. Gannal's method is much inferior to that of Suequet, of Paris, who used chloride of zinc. Falcony, of Paris, used external applications of zinc sulphate, without opening the body or injecting the arteries: after 40 days his subjects lost their flexibility and became mummified. Thénard describes Chaussier's method, by which saturation with a solution of corrosive sublimate was employed. A German preservative, which is said to render the dead body resistant of decay for several years, while it retains color, form, and flexibility, consists of alum, sodium chloride, potash, arsenious acid, and boiling water, with glycerin and methyl alcohol. This liquid is used for both saturation and injection. An impetus was given to embalming in this country by the successful work of Dr. Thomas Holmes, of Brooklyn, N. Y., who prepared and sent home many dead soldiers from the battlefields during the Civil War. Embalming is steadily taking the place of the use of ice in preserving the dead until funeral services and interment are ended. There are two reasons for its employment: (1) preservation of the body for transportation or leisurely disposal; (2) sanitation, for it is an absolute prevention of communication of infection, either before the body is buried or after it has crumbled and mingled with the earth in a cemetery. About four quarts of fluid are used for a body, some of which is injected into the arterial system, some into the cavities of the

pleuræ, peritoneum, and pericardium, and some is used for saturation. Discolorations are removed by various processes. The composition of the embalming fluids used to-day in the United States appears to be a secret known only to the undertakers' supply companies; it is believed that they contain arsenic, alkalies, and alcohol.

E. Smith, *A Contribution to the Study of Mummification in Egypt* (Cairo, 1906); Myers, *Champion Text-Book of Embalming* (5th ed., Springfield, Ohio, 1908); Eckles, *Practical Embalmer* (Philadelphia, 1904); id., *Sanitary Science* (ib., 1904); Nunnemaker and Dhonau, *Hygiene and Sanitary Science* (Cincinnati, 1913).

EMBANKMENTS. In engineering, masses of earth, rock, or other materials artificially formed and rising above the natural surface of the ground. They are built chiefly either to carry railways, common roads, canals, etc., over depressions or for hydraulic purposes, such as the formation of dams and reservoirs, or for defenses against the overflowing of rivers and the encroachments of the sea or lakes. The form and dimensions of embankments and the materials and methods of construction adopted depend upon the purpose for which the embankment is to be used. In all cases except where they are confined by external constructions, such as retaining walls, embankments are trapezoidal in section, with a broad base and a narrow top connected by sloping sides. The material employed in embankments varies from almost any available mixture of rocks and earth or other fragmentary material used in railway embankments to very carefully selected, finely divided earths used in forming water-tight embankments for dams, reservoirs, dikes, levees, and canals. The method of construction likewise varies from a mere dumping of the material in place to be roughly leveled off and allowed to settle under action of the elements, to a careful building up of the selected material in layers a few inches thick which are carefully compacted by ramming or rolling. Embankments for dams and reservoirs are instances where the more careful methods are employed. Embankments for railways are examples of less careful methods of embankment construction. In constructing embankments it is usually necessary, as a basis upon which to determine the cost, to calculate their volume. For preliminary estimates the methods of determination by average end areas or middle areas are used, but for more exact work the prismoidal formula is employed. Consult Johnson-Smith, *Theory and Practice of Surveying* (17th ed., New York, 1910), and Taylor, *Prismoidal Formulas and Earthwork* (ib., 1898); See DAMS AND RESERVOIRS; LEVEES; RAILWAYS.

EMBARGO (Sp., seizure). A legislative act or executive decree directing the detention in port of vessels, whether foreign or national. It may be for the purpose of using the detained shipping for naval operations, or in the event of some projected expedition to insure secrecy, or with a view to temporary nonintercourse with some foreign nation, or by way of reprisal. A hostile embargo by one nation prohibits the

departure from its ports of vessels belonging to another with which it is at variance, for the purpose of securing a favorable settlement of the dispute and, in case of war, of having an opportunity to make reprisals. While the right to lay such an embargo is still generally recognized, the practice is generally disapproved and is seldom employed by civilized states. A civil embargo aims at nonintercourse and is laid pursuant to plans of public policy, or for the protection of the merchant vessels of a neutral nation against the attacks of belligerents, or by its interference with a belligerent's commerce, to restrain it from acts prejudicial to the trade of the neutral power. Consult the authorities referred to under INTERNATIONAL LAW.

The first embargo in the history of the United States was laid on March 26, 1794, in retaliation for the British orders in council dated June 8, 1793, and Nov. 6, 1793 (see ORDERS IN COUNCIL), and remained in effect for 60 days. Subsequently, during the wars between France and Great Britain, successive French decrees and British orders in council drove the United States, by way of reprisal, first to the passage of a nonimportation act (April, 1806), and finally to the laying of another and stricter embargo, Dec. 22, 1807. This latter measure was intended completely to prevent American vessels from . . . foreign commerce and naturally met . . . opposition in the New England States, where the commercial element of the country was almost wholly concentrated and where, besides, a large majority of the influential classes was affiliated with the Federalist party and was thus predisposed to attack the measures of the Republicans, then in power. Though there was undoubtedly much smuggling on the part of New England merchants and shipowners, commerce suffered enormously, and the exports of the country fell from \$108,343,156 in 1807 to \$22,430,960 in 1808. The opposition, indeed, became so pronounced that in many quarters nullification was openly advocated, and stanch Federalists unhesitatingly gave their approval to doctrines closely allied to those embodied in the Virginia and Kentucky resolutions (q.v.) of Madison and Jefferson. By some, indeed, secession was openly threatened. As a measure for bringing Great Britain and France to terms, moreover, the embargo proved futile, neither power being injured to anything like the same extent as the United States; and in February, 1809, Congress, alarmed at new manifestations of popular discontent in New England, passed a resolution providing for the termination of the embargo on March 4. Nonintercourse measures were then put into force and were the chief feature of the foreign policy of the government until the outbreak of the War of 1812. After the beginning of hostilities it soon became evident that the British government would endeavor to procure fresh provisions from the New England States; and Congress again laid an embargo, Dec. 17, 1813, to remain in force until Jan. 1, 1815. On April 14, 1814, however, this embargo also was repealed. It is now pretty generally agreed that the laying of the embargo was a great political and economic mistake, and it is certain that, as a result of it, American shipping sustained between 1807 and 1815 almost irreparable damage. Consult: Adams, *History of the United States from 1801 to 1817*, vol. iv (New York,

1889-91); McMaster, *History of the People of the United States*, vol. iii (ib., 1883); Randall, *Life of Jefferson*, vol. iii (ib., 1858); Schouler, *History of the United States*, vol. ii (rev. ed., ib., 1899).

EMBASSY (from OF., Fr. *ambassade*, from OSp. *ambawada*, Sp. *embajada*, from ML. *ambaxiata*, *ambassiata*, *ambawia*, *ambassia*, *embassy*, from Lat. *ambactus*, servant). The mission and entourage of an ambassador accredited to a foreign state. In a popular sense all diplomatic missions are spoken of as embassies, but, strictly speaking, an embassy is a mission presided over by an ambassador as distinguished from a mission or legation intrusted to a minister, envoy, or other inferior diplomatic agent. The term "embassy" comprehends, besides the ambassador, who is its head, all of the members of his suite or official family, which always includes a secretary of legation, and often a private secretary, a chaplain, and a physician. All of these, as well as the members of the ambassador's private family, enjoy certain privileges and immunities in the state to which they are accredited. (See AMBASSADOR; DIPLOMATIC AGENT.) The term "embassy" is sometimes, like the corresponding term "legation," popularly, but inaccurately, applied to the official residence of a foreign ambassador.

EMBATERION (Gk. *ἐμβάτηριον*, from *εμβαλεῖν*, *embainein*, to enter, from *ἐν*, *en*, in + *βαλεῖν*, *bainein*, to go). A Greek war song, sung in marching time, to the accompaniment of the flute, while the advance was being made upon the enemy. We have scanty fragments of such songs, ascribed in ancient days—without reason, however—to Tyrtæus, in anapestic measure. Consult Christ-Schmid, *Geschichte der griechischen Litteratur*, vol. i, p. 163 (5th ed., Munich, 1908).

EMBAT'TLED, or **IMBAT'TLED** (from OF. *en*, in + *bastiller*, to build, from *bastir*, Fr. *bâtir*, to build; confused by popular etymology with *embattle*, to range in line of battle). In heraldry, a term applied to a partition line, traced in the form of the battlements of a castle or tower, called also *crenelle*. A bordure embattled is often given as a difference to any member of a family who is, or has been, a soldier.

EMBDEN GOOSE. See GOOSE.

EMBER DAYS (AS. *ymbren-dæg*, from *ymbren*, *embryne*, circuit, from *ymb*, *embe*, OHG. *umbi*, Ger. *um*, around + *ryne*, course, from *rinnan*, to run, and *dæg*, Goth. *dags*, Icel. *dagr*, OHG. *tac*, Ger. *Tag*, day). Fast days observed at the four seasons of the year by the Roman Catholic church. The earliest certain reference to their use is by St. Leo the Great (440-61); in his time, however, they were of local Roman, not universal, observance and date from the agricultural ceremonies of pre-Christian Rome. Since Pope Gelasius (492-96) fixed the ordinations at these seasons they have been considered times of special prayer for the sending forth of worthy laborers into the Lord's vineyard. The observance of them seems to have been introduced into England by St. Augustine and into Germany by St. Boniface. Their exact date has varied; they are now the Wednesday, Friday, and Saturday after the first Sunday in Lent, after Whitsunday, after September 14, the Exaltation of the Cross, and after December 13, St. Lucy's Day. In the Church of England, the ordination of clergy generally takes place on the Sundays following the ember days. Em-

ber weeks are the weeks in which the ember days fall. Consult Duchesne, *Christian Worship* (London, 1904). See FAST.

EMBER GOOSE (Dan. *imber*, Ger. *Imber*, ember + goose), or **IMMER GOOSE**. A Hebrew name for the loon.

EMBEZZLEMENT (from *embezzle*, from OF. *imbecile*, *imbecille*, Fr. *imbécille*, weak, imbecile, from Lat. *imbecillis*, weak). The fraudulent appropriation of money or other personal property held in some fiduciary capacity, as that of agent, clerk, or servant. As a crime, the offense is purely statutory. The wrongful act of misappropriating funds or other property in one's possession being, at common law, only a civil wrong (known as conversion), the remedy for which was an action of *trover* for the damages sustained. The common-law crime of larceny was committed only by one who with felonious intent took personal property out of the possession of another. The American statutes upon this subject are based chiefly upon the English Statute of 8 Geo. IV. In addition to the provision that the article taken should not have been taken from the possession of the employer, that act required, in order to sustain a charge of embezzlement: (1) that the accused should be a clerk or servant, or a person acting in such a capacity; (2) that the property should have come into his possession "by virtue of his employment"; (3) that he fraudulently converted, or appropriated, or secreted it for his own use, without the consent or concurrence of his employer, and with intent to convert it to his own use. Although that act confined the crime to servants, clerks, and persons employed in such capacity, yet the laws are now broad enough in scope, both in England and in most of the United States, to include wrongs of this nature committed by such persons as agents, attorneys, factors, brokers, public officers, trustees of charities, directors and officers of corporations, etc. If however, the relation of debtor and creditor simply exist between the owner of the articles appropriated and the person who appropriates them, so that he who receives them may, if he choose, regard them as his own and thus make himself liable to respond to his employer for their value, the act will not be an embezzlement. If the property come into the possession of the wrongdoer in any other manner than "by virtue of his employment," his retention of it, however wrongful, cannot constitute the crime of embezzlement. The essential element of the crime in this respect is that some confidence shall be violated. Thus, if a servant, believing himself authorized to receive money for his master, but not being in fact so authorized, receive it and convert it to his own use, he does not commit the offense. By the statutes of some American States it is not necessary, in order to constitute this crime, that the property belong to the employer, so long as it does not belong to the servant or clerk and is acquired by the wrongdoer by virtue of his employment.

If a person commit the necessary act of conversion, or appropriation, the presumption is that he meant to embezzle. Still there must be a criminal intent; and if it be proved that the accused honestly believed himself entitled to the property intrusted to him, however much mistaken he may have been, he cannot be convicted of the crime.

In England one indicted for larceny (q.v.)

may now be convicted of embezzlement if that crime only be proved, and vice versa. In some American States, as New York, larceny has been made broad enough to include embezzlement. The punishment prescribed for the crime is imprisonment for a term of years. This varies somewhat in different jurisdictions, the minimum term being usually not less than two years and the maximum from 10 to 15 years. Consult: Stephen, *History of the Criminal Law of England* (London, 1883); Rapalje, *Treatise on the Law of Larceny and Other Kindred Offences* (Chicago, 1892); and the authorities referred to under CRIMINAL LAW.

EM'BLA (Icel., possibly connected with *almr*, elm). In Norse mythology, the name of the first woman created. According to the Elder Edda, the gods Odin, Hœnir, and Lodur, when wandering on the earth, found Ask (ash) and Embla (elm) without power and without destiny. They had neither spirits, nor sense, nor blood, nor power of motion, nor fair color. Odin gave them spirit, Hœnir sense, and Lodur blood and fair color. The Later Edda gives the names of the gods as Odin, Veli, and Ve. The man they called Ask, and the woman Embla. From this pair the human race descended; a dwelling was given them in Midgard (the earth).

EM'BLEM (Lat. *emblemata*, Gk. *ἐμβλημα*, *emblemata*, from *ἐμβάλλειν*, *emballlein*, to inlay, from *ἐν*, *en*, in + *βάλλειν*, *ballein*, to throw). A representation of an object intended to signify or indicate to the understanding something else than that which it directly represents to the eye. The meaning of the emblem rests upon its secondary, not its primary, signification. Emblem is often used in a sense synonymous with "symbol." See SYMBOLISM.

EMBLEM'ATA. The ornaments in relief with which gold and silver vessels were decorated by the ancients. These figures were generally executed either in the precious metals or in amber and could usually be taken off at pleasure. They were also called *crustæ* by the Romans.

EM'BLEMENTS (OF. *emblaement*, from *emblaer*, *embleyer*, *emblader*, Fr. *emblaver*, to sow with grain, from ML. *imbladare*, to sow with grain, from Lat. *in*, in + ML. *bladum*, grain, from Lat. *ablatus*, p.p. assigned to *auferre*, to bear away, from *ab*, away + *latus*, OLat. *tlatus*, carried, *tollere*, Gk. *τῆλαι*, *tlēnai*). Growing crops of cereal and vegetable products raised by the labor of the cultivator. Fruits of trees growing on the land and grass growing from the ancient roots are not emblems. By the common law, when a tenant for life died after the planting and before the reaping, his personal representative was entitled to the crops. In England and the United States a tenant for life or tenant at will whose term may be unexpectedly brought to a close is entitled to reap the crop which he has sown and to enter the lands after the expiration of the term to remove the emblems. The right of life renters in Scotland to reap the growing crop resembles the English right to emblems. In America emblems are sometimes known as "way-going crops." See LIFE ESTATE; TENANCY AT WILL.

EM'BOLISM (Lat. *embolismus*, embolism, from Gk. *ἐμβόλιμος*, *embolimos*, intercalated, from *ἐν*, *en*, in + *βάλλειν*, *ballein*, to throw). The term employed by pathologists to designate the plugging up of a vessel by a clot of coagulated blood fibrin, by a detached shred of a

morbid growth from a diseased cardiac valve, detached atheromatous plates, fat globules, portions of tumors, masses of bacteria, or parasites. Clots, or portions of a clot, may be transported by the blood current from the venous system to the right side of the heart and block up the pulmonary artery either entirely or in part; if the occlusion is entire, sudden death is produced; if it is only partial, gangrene, or localized pneumonia, commonly ensues. Similar accidents may happen in the arterial system. A detached fragment of a diseased tricuspid or aortic valve of the heart, or a separated fragment of coagulated fibrin, may be driven onward in the blood current and enter and occlude some of the cerebral arteries, causing softening of the brain by cutting off the due supply of nourishment. It is a frequent cause of sudden death, carelessly ascribed to "heart failure," a recognized cause of apoplexy (q.v.), with subsequent paralysis. Consult: Geigel, *Gehirnhämorrhagie und Embolie* (Berlin, 1902); A-chaff, *Beitrag zur Thrombosefrage* (Leipzig, 1812); Starr, *Organic and Functional Nervous Diseases* (London, 1913). See THROMBOSIS.

EMBOLITE. A chlorobromide of silver occurring in greenish isometric crystals. It is one of the principal ores in the Chilean silver mines. It is also found at Eulalia, Mexico; at Coloal, in the Province of Gracias, Honduras; and in Victoria and New South Wales.

EMBOSSING (Fr. *embosser*, from *en*, in + *bosse*, hump, bump, OHG. *bōzo*, tuft, from *bōzan*, Ger. *bossen*, to beat). The art of producing figures in relief upon various substances, including paper, leather, wood, and metals. This is usually effected by pressing the substances into a die, the kind of die and mode of applying being modified by the nature of the design and of the material to be embossed. (For the stamping of sheet metal, see DIES AND DIE SINKING.) Embossing of metal, however, may also be done by hand by beating up the metal from the underside, in which case the process is called *repoussé* work. See REPOUSSÉ.

Paper and cardboard are embossed with dies in a similar manner, but the dies are frequently of brass, sometimes of copper electrically deposited and suitably backed. The counterdie is commonly made of soft metal, card, or millboard, pressed into the metal intaglio die until a sharp impression is produced. The paper or card is well damped and a fly press is generally used. The leather or cloth for bookbinding is embossed in this manner, the counterdie being usually made by gluing several pieces of millboard together and gluing them to the upper bed of the press, then stamping these into the lower die until a perfect impression is obtained. The embossing press designated for impressing the medallion upon postage envelopes is a very elaborate and beautiful machine, which inks the die itself, and with the aid of two operatives to place and remove the envelopes embosses 60 envelopes in a minute. When large surfaces of textile fabrics, such as table covers, etc., have to be embossed, the fabric is compressed between rollers, one being of metal upon which the device is sunk like a die; the counter roller or bed cylinder is of paper covered with felt; this yields sufficiently to allow the fabric to be pressed into the die cylinder. A third smooth metal roller is commonly used to press out again the impression made upon the bed cylinder; this acts upon the bed cylinder on the side from which the fab-

ric emerges. Paper is sometimes embossed in this manner; and the flattening roller may be dispensed with if the cylinders are sufficiently accurate in their diameters for the pattern always to fall on the same place at each successive revolution. Leather embossed in high relief for ornamental purposes is sometimes stamped with dies of type metal or electrically deposited copper, the leather having first been softened in water. Several methods have been invented for embossing wood. Sometimes hot molds are pressed upon the wet wood, which burn in the pattern, the charcoal being afterward removed. In some machines engraved rollers are used instead of stamps, the wood being steamed and passed between the rolls while hot. In another method the wood is pressed and rubbed with a blunt instrument, the surface yields, and a depression of some depth is made; if the wood be now soaked in water, the depressed portion will rise to its original level. Only the surface in those parts that are to be finally in relief is rubbed down. The rest of the surface is planed down even with the depressions and the wood soaked; this causes the compressed parts to swell back to their original level and stand out in relief against the planed surface. Embossing in needlework is effected by embroidering over figures padded with wool felt or other material.

EMBOWED, *ēm-bōd'*. The heraldic term for anything which is bent like a bow. A sinister arm couped at the shoulder is embowed. When the arm is turned the reverse way, it is said to be counterembowed.

EMBRA'CERY (from OF. *embraser*, *embracer*, Fr. *embraser*, to kindle, from *en*, in + *braise*, live coals, from Dan. *brase*, to fry, Icel. *brasa*, to harden by fire). The criminal offense of attempting to influence improperly a juror in a civil or criminal action, or one summoned as a juror, or an arbitrator, or a referee in respect to his verdict, award, or decision. Any means of swaying his judgment other than evidence or argument in open court is deemed improper. Hence a juror who attempts corruptly to influence his fellow jurymen commits this offense. As the gist of the crime is the attempt, it is not necessary that a juror, arbitrator, or referee be actually affected by the criminal's acts, nor that a verdict or decision be rendered in accordance with the improper solicitation. It is generally spoken of as a common-law misdemeanor, although it has been dealt with by statute in England since 1360 and is defined by statutes in this country. As a crime against public justice it is recognized everywhere as a heinous offense and is punishable by fine or imprisonment. Consult the authorities referred to under CRIMINAL LAW.

EMBRASURE (Fr. *embrasure*, from OF. *embraser*, to skew, from *en*, in + *braser*, to skew). An aperture, in the wall or parapet of a casemate or other fortification, through which guns are fired. A similar smaller opening for the use of small arms is usually called a loophole, or notch. A loophole has overhead cover; a notch has not. A crenelle (Lat. *crena*, a notch) is an embrasure in a battlement. Embrasures are usually so skewed or played as to obtain the maximum arc of fire with the maximum protection to the firer. The bottom of an embrasure is called the floor, or sole; the sides, the cheeks; the narrowest part of the opening, the throat; the angle of divergence of the sides, the splay.

EMBROID'ERY (from OF. *embroder*, from *bord*, border). The art of ornamenting cloth and other materials with needlework. But flat ornaments *woven* directly into the warp, like those on the fragments of linen robe found in 1903 in the tomb of Thothmes IV (fifteenth century, B.C.), and in many Coptic and Peruvian textiles, are tapestry; and embroidery on net and cutwork belongs with lace.

Historical Development. Embroidery in its crudest form is one of the oldest of the decorative arts. It was probably applied to skins before the art of spinning and weaving had been developed, and almost as soon as the use of the needle and thong for joining together skin garments was developed. Among the primitive tribes of Central Africa the girls embroider skins with figures of flowers and animals, bright shells and feathers also being used in their decoration. The Laplander embroiders upon his reindeer-skin garment with a needle of reindeer bone, thread of reindeer sinews, and appliqué of strips of hide. Of the textiles of ancient Babylon and Assyria no fragments have survived. But the Nineveh mural reliefs in the British Museum show Assyrian robes with both geometrical and floral ornament, and the famous relief now in the Louvre from the palace of Darius I (521-485 B.C.) shows Persian robes with diaper pattern. These ornaments, like those of the hangings of the tabernacle described in the Book of Exodus, may have been either embroidery or tapestry. Among the ancient Greek textiles exhumed from Crimean graves are both tapestries and embroideries, now preserved in the Hermitage at St. Petersburg. One of the embroideries attributed to the fourth century B.C. is in colored wools on wool and shows a cavalier with honeysuckle ornament. Also among the Romans embroideries and tapestries were used side by side.

Marzial, in the first century A.D., writes that the embroideries of Babylon have been driven out of fashion by the tapestries of Egypt (*victa est pectine Niliaco iam Babylonis acus*). After Byzantium (Constantinople), at the beginning of the fourth century A.D., was established by Constantine as the capital of the Roman Empire in place of the city of Rome, embroideries elaborate with gold were used on secular as well as on ecclesiastical robes. Preserved in the sacristy of St. Peter's at Rome is a blue silk garment, probably Byzantine work of the twelfth century, known as the "dalmatic of Charlemagne." Embroidered on the front is the Triumph of Christ, on the back the Transfiguration, both with captions in Greek. The comparatively brief textile prominence of Palermo in Sicily, with Saracenic workmen, under Norman kings, is commemorated by richly embroidered Imperial coronation robes preserved at Vienna and described in Bock's *Kleinodien*. In the library of the English cathedral of Durham are fragments found in the tomb of St. Cuthbert, embroidered in gold in the tenth century.

In the public library of the French town of Bayeux is preserved the famous Bayeux Tapestry (q.v.), which is not a tapestry at all, but an embroidery. Very beautiful are the Italian embroideries of the fourteenth century. One of the finest, a richly colored altar frontal in gold, silver, and silk, preserved in the Florence Archaeological Museum, is signed *Jacobus Cambi de Florentia me fecit MCCCXXXVIII* (James

Cambia of Florence made me in 1338). Among fifteenth-century Italian embroideries are those in the Opera del Duomo in Florence picturing the story of St. John, attributed to the design of Antonio Pollaiuolo. In the Cluny Museum is a sixteenth-century Italian embroidery after Raphael which pictures the Israelites worshipping the golden calf. It is an oval, 20 by 32 inches, the only piece remaining of a furniture set with gold ground, picturing 40 scenes from Hebrew history, preserved at the abbey of Saint-Denis until the French Revolution. In early Spanish embroideries Moorish influence was strong, and East Indian influence in Portuguese embroideries. Early German embroideries cling close to Byzantine traditions, keeping the draperies flat without folds and covering them with pattern.

As in tapestry, so also in embroidery, the Germans made much use of long narrow bands to hang above choir stalls, with story told in sequence of scenes and descriptive captions. An eleventh-century Danish embroidery is the one, in the church at Odense, covering the relics of King Canute (1080-86).

In the Netherlands in the fifteenth century, under the Duke of Burgundy, embroidery flourished, as did tapestry and painting, and both textile arts utilized the designs of the best painters. Among the best examples of the period are the *ornement de la toison d'or*, a set of vestments now in the Hof-Museum at Vienna; and the red velvet cope, with orphreys and hood picturing the seven works of mercy, in the museum at Tournai. In the seventeenth century and after, the embroideries of Holland were much influenced by the Dutch conquests in the East Indies, and many embroideries were produced in the Far East, under Dutch direction, for exportation to Holland.

An exquisite French embroidery of the fifteenth century in the Museum of Chartres is in the form of a triptych with a Pietà in the middle, St. John the Evangelist on the left, and St. Catharine of Alexandria on the right. In the sixteenth century in France were produced many ornamental embroideries without figures—velvet, satin, or silk florals and scrolls on woolen. Splendid examples of seventeenth-century French embroidery are the vestments given by Louis XIII to the cathedral of Reims and still preserved there. Louis XIV not only had many embroiderers attached to his household, but also installed others at the Gobelins, whose duty it was to make draperies and furniture coverings; among these embroiderers were Simon Fayette, whose specialty was figures, and Philibert Bolland, whose specialty was landscapes. In the thirteenth century English embroidery was celebrated throughout western Europe, and the phrase *de opere anglicano* occurs constantly in inventories. The most famous example is the Syon cope in the Victoria and Albert Museum at South Kensington. It is covered with embroidered medallions picturing Christ on the cross, Christ and Mary Magdalen, Christ and St. Thomas, the death of the Virgin, the burial and coronation of the Virgin, St. Michael, and each of the Twelve Apostles separately. The spaces between the medallions contain six-winged cherubim. The figures are in gold, silver, and colored silk, with medallion grounds of green silk embroidery between medallions. The orphrey with coats of arms and the lower border are of later date. The cope takes its name

from the convent of Syon, near Isleworth, to which it formerly belonged, being taken to Portugal at the time of the Reformation and not brought back to England until the nineteenth century.

During the fourteenth and fifteenth centuries many excellent ecclesiastical embroideries were produced in England, and in the sixteenth century the costumes of the nobility were magnificent with embroidered florals. Black work, done in silk or linen, was popular in the reign of Elizabeth. So also was petit point, sometimes called tapestry or needlework tapestry, an all-over cross stitch on coarse canvas in imitation of woven tapestry.

Richly costumed figures were introduced, often in small medallions in fine point on a ground of coarse point. During the seventeenth and eighteenth centuries petit points in floral and purely ornamental designs continued to be made in England for use as draperies and furniture coverings and sometimes as framed pictures. During the latter half of the nineteenth century embroidery shared the revival of interest in decorative art (q.v.), and artists like William Morris, Burne-Jones, and Walter Crane supplied designs. But the majority of embroideries made to-day are either copies of ancient ones (some of them intended for sale as antiques), or purely ornamental patterns produced at small expense on the bonnaz or other machines in Switzerland, Saxony, and elsewhere.

The people of the Orient continue, as in ancient times, to excel in the art of embroidery, and the woolen shawls of Cashmere are still world famous. The Chinese are perhaps the most laborious and elaborate hand embroiderers, their best work being in silk. The figures are either in colored silk alone or combined with gold and silver thread; sometimes the figures of men, horses, dragons, and the like are outlined in gold cord and filled up with shaded silk. The Persians, Turks, and Hindus use, besides silk and gold and silver threads, beads, spangles, pearls, and precious stones. Some of the Oriental embroideries include a still wider range of materials. Feathers are largely and very tastefully employed, and also the skins of insects, the nails, claws, and teeth of animals; nuts, pieces of fur, and skins of serpents are among the materials drawn upon. Coins, which are so commonly used as ornaments of the hair of unmarried women, are also worked into embroidery on their dresses. The Indian women embroider with their own hair and that of animals.

The Process of Embroidery. The tools of the embroiderer are the simplest, consisting of needles to draw the different kinds and sizes of thread through the work, a frame in which to hold the material (which may be omitted in small pieces of work), and scissors to cut the thread. A stitch is the thread left on the surface of the cloth after each ply of the needle. The most common forms of canvas stitch, with the needle passing through the interstices of warp and weft of the canvas, are cross stitch, tent stitch, Gobelin stitch, Irish stitch, plait stitch. Crewel stitch is a diagonal stitch used in outlining. Some of the other principal stitches are chain or tambour, herringbone (so called because of its resemblance to a fish's backbone), buttonhole, feather, rope, of which the French knot is a complicated form, satin, long and short, darning, and running stitch. About the twelfth century the modeling and padding of figures became

common; i.e., embroidery was performed by sewing onto the material as well as into it. Hence we have the couching stitch, used when one thread is sewed on with another; and appliqué work, where one piece of cloth is sewed onto another. To give effectiveness to the appliqué work, the figures are often padded.

EMBRUN, an'bren'. A town of France, in the Department of Hautes-Alpes, situated on a rock plateau, 2850 feet above sea level on the right bank of the Durance, 25 miles east of Gap (Map: France, S., L 4). The town is fortified and has an imposing appearance. The principal building is a cathedral of Notre Dame, a Gothic edifice, dating from the eleventh century, surmounted by a lofty Romanesque tower. There are also the archiepiscopal palace, now used as barracks, a college, and a hospital. Embrun manufactures broadcloth, counterpanes, hats, cotton yarn, and leather, and has a fair trade in farm implements. Pop. (commune), 1901, 3505; 1911, 3556. Embrun was the ancient Embrodunum, capital of the Caturiges, and an important Roman station. As early as the fourth century it was the seat of a bishop and, from the ninth century to the beginning of the nineteenth, of an archbishop. It was burned by the Moors in 966, again in 1573 during the religious wars, and in 1692 by the Duke of Savoy.

EM'BRYO (from Gk. ἐμβρυον, *embryon*, embryo, from ἐν, *en*, in + βρύειν, *bryein*, to swell). An rudimentary condition, or condition from which an organized being may be developed. In botany, the term is applied to the germ which forms within the ovule on fertilization, and which increases to become the principal part of the seed. The perisperm of the seed, being regarded as a mere store of nourishment for the embryo, is not considered to be part of the embryo; while the cotyledons are considered as essentially belonging to it, together with the plumule, the radicle, and the connecting parts. In animal physiology the term is applied to the unborn young from the time the impregnation of the ovule occurs up to the time of birth, thus including the fetus (q.v.). Larvæ and pupæ, as those of insects, however, are not considered to be embryonal forms. (See LARVA.) In mammals the embryo's existence begins with the formation of the male pronucleus, which consists of the head of a spermatozoon which has penetrated the zona pellucida and perivitelline space of an ovule and, entering the yolk, has lost its tail and middle portion and has enlarged as a result of absorption from the surrounding material. Around each pronucleus a clear spot is formed. Conception takes place when this penetration and initial change occur. From this spot protoplasmic lines radiate, forming the aster. The fertilized ovum is termed the oöperm. The next step in the development of the embryo is segmentation of the oöperm, i.e., active division of the yolk. A groove forms, dividing the oöperm into two parts. A second groove, appearing at right angles to the first, subdivides the original parts into four. Similar division follows, into 8, 16,

32, and still more numerous parts. A cleft filled with clear fluid makes its appearance in the interior of the mass, and this is called the segmentation cavity. A thickening of a part of the wall of the ovum (now termed a vesicle) appears, oval at first, pear-shaped later. This structure is called the embryonic area, or germinal area, and from this the young animal develops in successive stages. An interesting embryonal structure is the amnion. This is developed from the upper leaf of the vesicle membrane, which arises in a ridge about the embryo. This ridge, by a continuous growth upward, arches over the back of the embryo, and its opposing edges meet and unite. This enveloping membrane is called the amnion. Between it and the foetus appears the amniotic fluid. In some instances a piece of the amnion tears off from the rest of the membrane, enveloping the head of the child as it emerges from the vagina. Such a portion of the amnion is called a caul.

There are many foetal conditions which are modified about the time of birth. For example, the circulation of the blood of a human embryo differs in many important respects from that of the adult. In the foetus the blood returning from the placenta by the umbilical vein divides into two currents. One of these passes through the ductus venosus to the inferior vena cava and thence to the right auricle of the heart, while the other proceeds to the liver through the hepatic vessels and thence to the right auricle. A limited supply of blood is forced into the right ventricle during contraction of the heart, while the greater part of it passes from the right auricle through the foramen of Botall (foramen ovale) into the left auricle. From the right ventricle some blood passes through the pulmonary artery, but most of it proceeds through the ductus arteriosus into the aorta. In the aorta this blood mixes with that coming from the left auricle and pulmonary veins. Blood is returned to the placenta by the umbilical vein. After birth obliteration of the umbilical vessels takes place. The ductus venosus becomes a fibrous cord, the foramen between the auricles closes, and the ductus arteriosus becomes also obliterated. For other developmental processes in the growth of the embryo, see EMBRYOLOGY; EMBRYOLOGY, HUMAN.

EMBRYOLOGY (from Gk. *ἐμβρυον*, *embryon*, embryo + *-λογία*, *-logia*, account, from *λέγειν*, *legein*, to say). That branch of biological science which deals with the formation and development of individual organisms. The starting point of development is a germ cell, which may be an egg, or a bud, or a fragment of the body of another individual. But all processes of development, being due fundamentally to the same causes, present sufficient similarity to be classed together as "embryological processes."

A germ cell, or sexual cell, may be generally defined as any cell which can, either alone or by fusion with another cell, reproduce the entire organism. The germ cell is, on the one hand, a specialized cell, told off for reproduction, and, on the other, an undifferentiated one, because it has the capacity of giving rise to the whole body. Sexual germ cells are of two kinds, essentially alike in the beginning, when they react similarly to microchemical agents; but later they gain a chemical difference. The one kind acquires a great size, deposits much yolk in its protoplasm, remains passive, and is an

egg; the other remains of small size, but gains a powerful locomotor organ, called a tail lash or flagellum, and is a spermatozoön.

Unicellular Development. At the outset it may be well to consider a case of development in the Protozoa, or unicellular animals, in order that we may learn to distinguish between the essential and the secondary in the process. We may take as a type *Podophyra*, one of the Suctorians. *Podophyra* produces germs of new individuals by the nipping off from the cell body of a spherical mass, including a nucleus. At the time that it is set free the germ possesses a girdle of cilia by means of which it swims about. It grows, i.e., increases in size. Finally it becomes attached at a point on the equator; becomes elongated, forming a stalk; develops sucking tentacles at the upper extremity of the body, and becomes an adult *Podophyra*. It is to be noted that: 1. The germ grows, and of course without any cell division occurring. 2. On the whole it becomes more complex as development proceeds; it is differentiated. 3. During development the embryo assumes various activities for which its organs fit it; it is adapted at every stage to meet the environmental conditions of that stage. Growth, differentiation, and constant adaptation to environmental conditions seem to be the essential characters of development.

Multicellular Development. In the Metazoa, in which the body is multicellular, the process of cell division has to be added to the developmental processes, but this may be regarded as a concomitant of the great size of the body, which demands nuclear material in every part. Here the germ cells may take the form either of an egg or of a spermatozoön.

Evolution of the Egg. The egg, or ovum, is the female reproductive cell especially modified for reproduction by being laden with a large amount of food, called yolk, intended as food for the young. The spermatozoön is the male reproductive cell, specialized in the direction of rapid locomotion, since it has to move to reach and pass into the passive egg. The egg has evolved from a condition in which the two reproductive cells (or gametes) were alike (*Paramecium*, *Spirogyra*). In other species the gametes are of different sizes, although both are motile. They are called macrospore and microspore. The former correspond to eggs and the latter to spermatozoa. In higher species, as in *Volvox* and the brown seaweeds, the macrospore becomes still larger and loses its motility. It has become a typical egg. Its increased size is due to the increased amount of food material stored in it.

Development of the Egg in the Individual. Eggs, like spermatozoa, arise from "primordial germ cells," which are early differentiated from the body cells and are at first of no definite sex. Only later, frequently under the stimulus of food, do the germ cells in certain individuals become male (spermatozoa), in others female (ova). In coelenterates the germ cells arise from either ectoderm or entoderm; in the higher groups from the lining of the body cavity. The primordial germ cells that are destined to form eggs become intimately associated with the adjacent tissue, from which they receive nutritive material and in consequence grow rapidly. At the same time the yolk material, which is composed of spherules united by egg plasma, is stored away in definite parts of the egg in the case of

those eggs that have much yolk. During this period the nucleus gets very large and has received the name of "germinative vesicle."

The egg is a cell and as such has nucleus and cytoplasm. It is usually invested by one or more membranes, especially when it is discharged from the body to develop free. In respect to the amount and distribution of yolk, eggs may be classified as (1) alecithal, or with little yolk and that evenly distributed; (2) telolecithal, or with yolk concentrated at one pole, e.g., the hen's egg; (3) centrolecithal, or with yolk at the centre, e.g., the eggs of most arthropods. See Egg.

The number of eggs that ripen at one time is variable in different species of animals. In many mammals, as in man, there is usually 1; in other mammals, 2 to 10. In birds the number varies from 1 to 20. Land turtles may lay 40 or 50 eggs. Many fish deposit several thousand eggs at one time.

Reduction Division and Polar Globules. Certain important changes in the nuclear structure of the egg precede fertilization. The process of fertilization would, if unrestrained, cause an enormous multiplication of chromosomes (see CELL) in descending generations. This is averted by the fact that, previous to or coincident with fertilization, and after the egg has acquired its characteristic great size, one or more (usually two) parts are cast out or segmented off by a sort of modified cell division from the egg. This casting out of the polar globules is the final act in the maturation or preparation of the egg for fertilization. It is an unequal cell division, since the polar globules are many times smaller than the egg. The division by which the polar bodies is produced is known as reduction division. The first polar body may divide at the time the second is extruded, so that we have as a result of maturation three abortive eggs and the mature egg proper, which, when fertilized, develops into the embryo. Up to the time of the formation of the polar bodies the number of the chromosomes is the same as occurs in the somatic cells. As the cell gets ready for maturation, however, the number of chromosomes is reduced to half the usual number, and each of the two polar bodies is split in half at the time of each polar globule. The polar bodies soon perish.

In the development of the spermatozoön a similar reduction occurs, but in the process no cells are destroyed. The result of reduction is that the ripe germ cells contain only one-half the number of chromosomes possessed by the cells of the body. This number is then restored in fertilization. The interpretation of reduction is obscure. As already suggested, it will permit of the union of new chromosomes without increase in amount. It has been suggested by Weismann that the process has this additional significance, that variation is produced in that certain of the parental qualities are eliminated from both sex cells, so that the combination resulting from fertilization will be different for every individual.

Fertilization of the Ovum. The eggs of most animals and plants require, before they begin their development, that a spermatozoön should penetrate into them. This act is known as fertilization.

General Facts and Conditions. The ovum being yolk laden, or embedded in nutritive material, is passive, and the spermatozoön has to

come to it. In many of the lower aquatic plants and animals the fertilization occurs in the water into which both kinds of sex cells have been thrown. In the higher plants the ovum is deeply buried in the maternal tissues, and in most land animals it lies in the oviduct at the time of fertilization. In plants the pollen grain sends down to the ovule a tube which conveys the spermatozoön, and in animals the spermatozoön reaches the egg in the oviduct by virtue of its locomotive capability. The egg fertilized in the oviduct is then either extruded, "laid," to develop outside of the body, or it undergoes its embryonic development within the mother.

Polyspermy. In the fertilization of most animals normally only one sperm cell enters each egg, but more may do so. The entrance of the first sperm cell causes the formation of a membrane, or the closure of the micropyle, or perhaps affects the egg chemically, so that all other sperm cells are excluded. In rare cases, however, several spermatozoa gain entrance to an egg. This is called polyspermy and, it is said, results in an abnormal development of the egg, such as double cleavage, and soon ends in arrested development. In the eggs of certain insects and elasmobranch fishes polyspermy is frequent and normal, but in these cases only one of the sperm cells normally unites with the egg nucleus. The supernumerary ones live for a time and may even divide, but their ultimate fate is obscure.

Cytological Details. Fertilization consists essentially of mixing together living matter from two individuals—living matter which is therefore dissimilar. This interpretation of the significance of fertilization is of rather recent date. The early embryologists thought the sperm gave a stimulus to, or "animated," the egg, and it was long thought that the fluid of the sperm and not the spermatozoön was the "fertilizing" agent; the spermatozoa, indeed, were regarded as parasites. It is now known that the essence of fertilization is the union of two cells, and probably especially the union of their nuclei; for the head of the spermatozoön is composed almost wholly of the nucleus, and it is especially the head that penetrates into the egg. The head is at first very small compared with the nucleus of the egg cell, but it rapidly swells with water as it enters the egg, and when the nuclei unite they are of about the same size. The two nuclei contain the same number of chromosomes (see CELL), so that when they unite the number of chromosomes is doubled in the nucleus, half being derived from the mother and half from the father. Thus maternal and paternal qualities are united in the fertilized egg and are united in equal amounts. This accounts for the equality of inheritance by the offspring from the two parents. In plants the fusion of nuclei derived from the ovule and from the pollen grain occurs in a fashion exactly comparable with that of animals. The pollen grain typically contains two nuclei, of which the second has been seen in some cases to unite with a second nucleus of the ovule, viz., the endosperm nucleus. As a result of this union, those structures of the seed that are derived from the endosperm seem to derive their qualities from the two parents. This result is most striking when the parents belong to different species, characterized by different kinds of endosperm.

Phylogenetic Origin of Fertilization. The periodical union of two cells is seen even among

the lowest animals and plants. In some cases the union is a permanent one, followed by rapid cell division and the production of new individuals. Sometimes, however, the union is a temporary one and is characterized only by the presence of nuclear material. It is a striking fact that even in the Protozoa a reduction of the chromatic material occurs before fertilization. It is clear, then, that a fertilization process is one of very great physiological importance to organisms.

General Sketch of Egg Development in Animals. Since the egg is a single cell, it

In eggs with unequal segmentation the blastula is formed of several layers of cells, and the hollow (the segmentation cavity) is partly filled with large yolk cells. In eggs, such as the hen's egg, that have much yolk and undergo partial cleavage, the cleavage cavity is reduced to a fluid-filled fissure bounded above by several layers of cells and below by yolk (see below—account of development of a chick).

Gastrula Stage. It is necessary next that the digestive cells should come to line a digestive sac, while the sensory and protective cells remain on the outside of the germ. This is

EMBRYOLOGY OF THE FOWL.

1. Earliest stage: surface of the germinal disk of an egg, showing initial segmentation, which begins at the centre and spreads towards the periphery, but does not quite reach the periphery. 2. First appearance of the groove or furrow (f). 3. Other furrows (f) appear, giving rise to a series of irregular areas, each representing a rounded mass. 4. Additional furrows (f) branch off and "arise" on the periphery, giving rise to a series of larger peripheral areas. This process continues, as indicated by the beginning of a new furrow. The resulting pattern is the "mammillated" surface of the egg. 5, 6, 7, 8, 9, 10. Longitudinal sections, the small (head) end of the embryo is at the top. 11. A transverse section through the centre of the embryo, showing the cerebrosplinal marrow (sp) and the downward growth of the body walls on each side; also the formation of the pleuroperitoneal canal (a'). 12. Longitudinal section at a more advanced stage. 13. Transverse section after the formation of the pleuroperitoneal canal (a'). 14. Longitudinal section at this stage. Lettering: a, amnion; al, allantois; ap, area pellucida; a', allantoic canal; au, allantoic umbilicus; f, furrow; hb, hind brain; mc, medullary canal; mb, mid brain; pf, primitive furrow; pr.s, hind part of the primitive furrow; pp, general pleuroperitoneal space; ps, yolk sac; vt, vitelline membrane. (After Balfour.) 15. A chick, 30-36 hours old after incubation: ap, area (area pellucida) of the germinal disk surrounding the embryo, which has formed about the line of the primitive furrow (see Fig. 2); fb, mb, hb, vesicles of the fore, mid, and hind brain; o.v., optic vesicle; pr.s, protovertebrae; mc, medullary canal, in the sacra region; pr.s, hinder part of the "primitive furrow"; a, amnion.

must divide repeatedly to give rise to the multicellular body. These early cell divisions of the egg constitute cleavage, and the cells are called cleavage spheres. After 8 or 16 cells have arisen, a central cavity begins to appear surrounded by these cells. The protoplasm exists as a wall around this cavity until 100 or more cells have arisen. The whole embryo at this stage is the "blastula," and the cavity is the blastula cavity. The individual is now a hollow sphere, frequently ciliated and capable of locomotion in water. In the simplest cases it is composed of one layer of cells and is the result of total segmentation of eggs not laden with yolk.

VOL. VII.—44

effected in a variety of ways (mentioned more particularly later), the simplest of which is the pushing in of the blastula wall at one pole, as one might push in the wall of a hollow tennis ball. This is the act of "invagination." The invaginated layer partly or wholly obliterates the blastula cavity; and a new cavity opening widely to the exterior is formed—the "gastrula" cavity, or primitive food cavity. This stage is known as the gastrula stage. It corresponds essentially to the adult condition of coelenterates. The outer layer in both the gastrula and the adult coelenterate is called ectoderm, or epiblast; the inner layer, entoderm, or hypoblast. From

the ectoderm are developed later by differentiation various organs, such as the nervous system, various sense organs, feathers, hair, and nails; while from the endoderm arise not only the digestive canal, but all its outgrowths, such as lungs, liver, etc., and also the notochord of vertebrates.

Germ Layers. In the higher animals the gastrula stage is quickly followed by one in which loose cells are formed that migrate into the blastula cavity; in their totality these migratory cells are called mesenchyme. Very often, too, especially in the higher forms, a double layer of cells, lying in contact with the ectoderm and endoderm respectively, is formed between the two primitive layers. This is called the mesoderm. The cavity in the mesoderm is the true body cavity, or coelum. The layers, ectoderm, endoderm, and mesoderm, are the so-called germ layers. The theory that they are homologous (i.e., strictly comparable) in all animals where they occur, and that they always give rise to the same organs, is the germ-layer theory—one that held sway in the last quarter of the nineteenth century. It has been essentially modified and partially abandoned in the face of facts.

By the time the germ layers are established the embryo in many cases, especially of aquatic animals, frees itself from the egg envelopes and becomes free living; this constitutes the larval stage. The larva is often very different from the adult in form and habits and is adapted to its peculiar environment. After living for a longer or shorter period as a larva, the embryo undergoes a rapid change of form, called metamorphosis (q.v.), which leads to the adult condition. The egg development of plants differs from the above in the absence of blastula and gastrula cavities and of membranes; the germ is a solid cell mass. We shall now consider in more detail the different stages in development.

The Media in which Development Occurs. In the lower invertebrates, fishes and *Amphioxus*, the egg develops chiefly in the water, into which the ripe egg and sperm are both thrown. In other cases, however, the embryo is especially protected by some means for a certain time during early development. Whether the egg develops away from the mother or in connection with the maternal tissues has a great influence upon development. In the higher plants the embryo is embedded in the maternal tissues.

Cleavage. The nature of cleavage depends upon the disposition and amount of yolk in the egg. The kinds of cleavage are classified as follows:

- I. Complete division—holoblastic cleavage.
 - (1) Alecithal eggs (with little or evenly diffused yolk)—cleavage equal.
 - (2) Telolecithal eggs (with yolk lying towards one pole)—cleavage unequal.
- II. Partial division—meroblastic cleavage.
 - (1) Telolecithal eggs—discoidal cleavage.
 - (2) Centrolecithal eggs (with yolk at centre)—superficial cleavage.

Equal cleavage is characteristic of sponges, some coelenterates, many worms, echinoderms, some mollusks, tunicates, *Amphioxus*, and the higher mammals. Unequal cleavage is characteristic of many coelenterates, worms, and mollusks, the lower fishes, and amphibians. Discoidal cleavage is found in cephalopod mollusks, elasmobranch and teleost (bony) fishes, reptiles,

birds, and the lowest mammals. Superficial cleavage is found in most arthropods. When the egg cell is not completely cleft (partial division), the "cleavage spheres" are not well defined basally, and the later stages are complicated and deviate from the typical conditions described above.

Gastrulation Reconsidered. Three principal types of gastrulation are recognized among animals: (a) *Invagination*, which, as the typical process, has been already referred to. In partial cleavage the yolk-laden cells cannot be pushed into the small cleavage cavity, and under these circumstances the ectoderm grows over the endoderm and gradually surrounds it completely; this process is known as "epiboly," in contrast to the typical embolic invagination that occurs in alecithal eggs. (b) *Delamination*. The cells of the one-layered germ divide into a superficial and a deep-lying layer of cells. The latter become the endoderm. This type of gastrulation occurs in sponges, various coelenterates, and some of the lower worms. (c) *Ingression*. At one pole of the one-layered germ, cells begin to migrate into the blastula cavity to form the inner layer. This process is found especially in hydroids. The aim of all sorts of gastrulation is the establishment of a two-layered germ containing a digestive cavity. (d) *Formation of mesoderm*. The mesoderm arises in a great number of different ways—sometimes as a pair of pouches or a series of paired pouches from the endoderm, sometimes from primitive "mesoblast" cells which arise very early; sometimes split off from the other germ layers. Indeed, the varied origin of the mesoderm, despite the similarity of the organs to which it gives rise, is one of the strongest bits of evidence of the inadequacy of the cell-layer doctrine.

It will not be practicable to go into the developmental history of all the groups. We will, however, consider in some detail the development of the chick. For the development of man, see EMBRYOLOGY, HUMAN.

Development of a Dicotyledonous Plant. The fertilized egg lies deeply embedded in the ovary in a sac—the embryo sac—filled with nu-

FIG. 16. ADVANCED EMBRYO OF CHICK.

all, allantois; am, cut edge of amnion; aus, auditory sac; f.br, fore-brain; fl, fore-limb; h.br, hind-brain; h.l, hind-limb; ht, heart; hy, hyoid arch; m.br, mid-brain; mn, mandibular arch; t, tail. (After Parker and Haswell.)

tritive fluid. The fertilized egg, or oöspore, develops by means of a series of transverse and longitudinal cleavages into a more or less ovoidal body, the embryo. Certain of the cells of the embryo may early become specialized to form a thread composed of a single row of cells and called the suspensor. By means of the suspensor the embryo is pushed out into the nutritive fluids of the embryo sac. As cell division proceeds, a peripheral layer of cells is differentiated,

FIG. 17. ADVANCED EMBRYO CHICK.

Condition on fifth day; *s*, shell; *a*, air chamber; *emb*, embryo, lying on the left side, with the head up; *am*, amnion; *all*, allantois, in the cavity between the amniotic layers and performing the chief respiratory function; *ar. vasc.*, vascular area (vitelline blood) gradually extending its ramifications over the yolk sac (*ys*) and absorbing its nutriment.

which is the epidermis; also an axial column of cells is often early discernible, with the root-cap cell or cells at the end next to the suspensor, and the stem tip at the opposite end. The cotyledons are early formed by a pair of lateral regions of cell multiplication. In some cases the plumule with its nascent leaves is already formed from the stem tip before germination. The seed may contain the embryo as a minute germ embedded in food material derived from the embryo sac and parts of the ovule (pepper), or the food material may have become absorbed by the embryo and be lodged in the cotyledons (bean).

Development of a Chick. The hen's egg, as laid, is a complex thing. The shell and albumen are extraneous substances, laid down around the egg proper, or "yellow of the egg," as it passes along the maternal oviduct. The yellow of the egg is usually, while it is still in the oviduct of the hen, only a single cell, which is immensely distended by food materials or food yolk. The nucleus lies in a thin sheet of protoplasm on top of the yellow. This nucleus divides, but the whole yolk does not, so that partial cleavage occurs, producing a disk of several cells at the time the egg is laid. This disk constitutes the cicatrix, or "scar" or "tread" of the egg, which can be readily seen with the naked eye. It is technically called the germ disk, or blastoderm, and consists of an upper and an under layer. Later a middle layer of cells arises, and the blastoderm is differentiated into a central transparent *area pellucida*, on which the embryo forms, and a peripheral *area opaca*, which is continuous with the central area and extends laterally until it surrounds the entire yolk (Figs. 1-4).

The Primitive Groove. Embryonic growth begins by the formation of a long depression in the middle of the germ disk, called "primitive

groove" (Fig. 15), which indicates the region where a modified gastrulation is beginning; also at the hinder edge of this disk a depression is seen, and cells pass forward between the ectoderm and yolk mass, and others are budded off from the yolk to form the endoderm. As the embryo grows longer, the posterior gastrula depression retreats backward and the median depression elongates. Almost simultaneously, from the region of the primitive groove, the mesoderm is produced to the right and to the left. A little later a rod of cells is cut off below the primitive groove, making the notochord, around which the vertebral column will later arise. At about 18 hours a pair of folds rise up at the right and left of the primitive groove. These are the medullary folds, and the depression between them constitutes the medullary furrow. The folds grow higher and arch over towards each other until a complete tube—the medullary or neural tube—is formed. This gives rise to the brain and spinal cord. By the middle of the second day of incubation the head of the chick is marked off by the enlarging brain, the trunk is completed at the tail end, and the mesoderm is seen to be composed of a series of paired blocks of tissue; these correspond to the metameric segments of the body and are called primitive somites. From them the muscles of the body wall will arise. Laterally the mesoderm exists as two thin plates or layers, one of which—the somatic layer—lies close to the ectoderm, and the other—the visceral or splanchnic layer—lies next the forming food canal. Between these layers lies the body cavity.

The embryo is now well outlined. The food canal has a roof, but its floor is a mass of yolk which the ectoderm has gradually enveloped below as well as above. The embryo is gradually raised up above the great mass of the yolk, which now appears as a sac pendent from the underside of the nascent intestine. The head rapidly enlarges; mouth and eyes appear; mesenchymatous cells are laid down around the notochord and form the bones of the vertebral column; the spinal nerves grow forth from the walls of the neural tube; kidney organs, heart, blood vessels, and appendages of the food tube arise in rapid succession (Figs. 5-14, 16, 17).

Amnion and Allantois. In the chick, as in reptiles and mammals, two special embryonic organs, in addition to the yolk sac, make their appearance early in development. These are the amnion and the allantois (qq.v.). The amnion is an envelope formed about the embryo, which begins as a fold of ectoderm and somatic layer that completely surrounds the embryo. This fold becomes more and more elevated and finally, as a wall encircling the embryo, folds over the embryo, making a dome whose zenith aperture constantly diminishes until it disappears. The space between the embryo and the amnion is filled with the "amniotic fluid." The allantois is an outpocketing from the hinder part of the food canal which, growing through the still wide-open body cavity, spreads out against the egg membrane. It serves as a respiratory organ, since blood vessels ramify throughout it in great profusion. These get the oxygen which is admitted through the pores of the eggshell and carry it back to the embryo.

As mammals, birds, and reptiles possess an amnion in their embryonic condition, these three classes have been united into a group called Amniota; while the term Anamnia is applied

to the remaining vertebrates (amphibians and fishes) not so provided—the Sauropsida of Huxley.

The Causes of Development. These are difficult to discover. In the eighteenth century the idea prevailed that development consisted merely in the unfolding or growing larger of a minute individual, preformed in the egg or sperm cell; likewise it was assumed that a new generation lay in the ovary of that little being, with still smaller individuals inclosed within their bodies, ad infinitum. This is called the box-within-box theory. But exact study of the egg and the processes of embryological development shows that such a miniature does not exist in the egg, and that development is not merely becoming larger. What is it that directs the course of development and determines at what point new organs shall arise? We do not at present know. It is generally believed that the course of development depends somehow upon the chemical constitution of nucleus and cytoplasm. As a piece of a hydra warps itself into an embryonic form and thereafter develops as the egg embryo develops, we must conclude that it is not so much the constitution of the egg or the sequence of cell divisions that determines the form as some internal "force" which acts throughout the entire organism. See EPIGENESIS; EVOLUTION (especially remarks under *Coöperative Evidences of Evolution*); FŒTUS; GERMULE; GERM PLASM; ONTOGENY; PREFORMATION; RECAPITULATION THEORY; VESTIGIAL STRUCTURES; ETC.

EMBRYOLOGY, HUMAN. Our knowledge of the development of the human embryo was in an exceedingly fragmentary condition until Wilhelm His, the distinguished German anatomist, published in 1885 his *Anatomie menschlicher Embryonen*. This was the first, and is yet the most important, work on human embryology. Previously there existed, here and there, isolated descriptions of the first two months of pregnancy. The difficulty in getting embryos renders progress comparatively slow. The number of good collections of human embryos is very small, the most important being those at Leipzig and Baltimore.

In development it is convenient to distinguish the three stages suggested by His, viz., the ovum, the embryo, and the fetus. The stage of the ovum embraces the first two weeks; the embryonal stage embraces the third, fourth, and fifth weeks, during which time the principal organs are developed; finally, in the fetal stage the embryonal features change to those of the

fœtus and full-term child. The average length of embryo and fetus at various stages is approximately shown by the following table:

AGE	LENGTH	
	In inches	In millimeters
2 weeks	0.1	2
3 "	0.2	5
4 "	0.3	8
5 "	0.4 to 0.5	11 to 12
6 "	0.6	16
7 "	0.8	20
8 "	1.0	25
3 months	2.0	50
4 "	3.9	100
5 "	7.9	200
6 "	11.8	300
7 "	14.6	370
8 "	18.7	425
9 "	19.7	500

Ovum Stage. There are no observations on normal ova of the first 9 or 10 days. It is evident from the material of the later part of the ovum stage that there is an early and precocious development of the chorion and villi.

FIG. 1. SECTION THROUGH OVUM.

Section through a portion of a human ovum, with an embryo 1.9 mm. long: *am'* amniotic cavity; *d*, yolk sac; *m*, epithelial plate; *e.ch.*, epithelium of chorion; *mes*, mesenchyma; *ent.*, entoderm; *sp.*, cleft in exocoelom. (After Peters.)

The youngest-known normal ovum was described by Peters in 1899. It is 10 to 11 days old and consists of a vesicle $3 \times 1.5 \times 1.5$ millimeters in size (Fig. 1). The vesicle is formed by the chorionic membrane, consisting of an outer layer of epithelial cells covered by numerous villi which are in contact with the uterine wall of the mother, and an inner layer of mesenchyma. Attached to this inner layer at one side is the small embryo but .19 millimeter in length. It is apparently simple in structure, consisting of an epithelial plate facing the small amniotic cavity. On the other side of the plate is a layer of mesenchyma, and projecting from this is the yolk sac lined by entodermal cells. The projecting embryo is surrounded by mesenchyma continuous with that lining the chorion. The epithelial plate of the embryo and the epithelium of the amnion were probably at an earlier stage continuous with the epithelium of the chorion and subsequently cut off by sinking down into the vesicular cavity. Already, then, in the youngest-known ovum the so-called three

primary germ layers are present. (See EMBRYOLOGY.) From the epithelial layer develop the epidermis of the skin and its appendages (hairs, nails, sweat glands, etc.), the central nervous system, and portions of the eye and ear,

FIG. 2. BEGINNING OF EMBRYO.

Median section of a model of an embryo, 1.54 mm. long: *am*, amnion; *am'*, amniotic cavity; *al*, allantois; *b*, pedicle; *c*, chorda dorsalis; *ch*, chorion; *cn*, neurenteric canal; *d*, yolk sac; *dh*, its cavity; *g*, *g*, blood islands; *h*, place where heart will develop. (After Spee.)

mouth and nose. From the middle or mesenchymal layer develop the skeletal, muscular, circulatory, and urogenital systems; and lastly, from the inner or entodermal layer, here represented by the lining of the yolk sac, develop the alimentary tract, trachea, and lungs, liver and pancreas, and bladder.

The next important human ovum described contained an embryo .37 millimeter in length, and about 11 days old, attached at one side by a broad pedicle. Along the centre of the epithelial plate is a slight groove, the first trace of the central canal of the central nervous system; and a small diverticulum of the sac (the allantois) projects into the pedicle (Fig. 2). A day later the circulatory system has begun to develop, as a simple tubular heart lying in the mesenchyme between the head end of the embryo and the yolk sac. From the head end of the heart is given off the aorta, which divides im-

FIG. 3. AN EARLY EMBRYO.

Lateral view of the model of embryo of 2.1 mm. long: *am*, amnion; *al*, allantois; *br'*, *br''* first and second gill pockets; *b*, liver rudiment; *h*, heart; *d*, yolk sac. (After Mall.)

mediately into three pairs of arches that pass around the primitive fore-gut to unite beneath the medullary plate into the dorsal aorta. Blood vessels extend between the embryo and chorion. The yolk sac has now become somewhat constricted along its attachment to the embryo,

leaving pockets of the entoderm under the head and tail ends of the epithelial plate, which form the primitive fore-gut and hind-gut. The medullary folds, which are the first rudiments of the central nervous system, are now well marked, as also is the groove lying between them. Just beneath the epithelial plate, and lateral to the medullary folds, the mesenchyma is divided into 13 pairs of segments, the first differentiation for the muscular system.

At the age of two weeks many important changes have taken place. The embryo has greatly increased in length and is curved into a semicircular form (Fig. 3). The medullary plate is converted into a thick-walled tube, and the groove into its canal. At the anterior end of this tube are enlargements marking the beginnings of the brain, while the remainder of the tube forms the spinal cord. From the fore-gut has arisen the pharynx with two gill pockets and a thyroid pocket, but the main portion of the alimentary tract is still embodied in the large yolk sac. The forebrain of an embryo about 14 days old has a marked ventral bend, and between the forebrain and the heart is an invagination of the skin to form the mouth cavity, not yet connected with the pharynx. Projecting from the forebrain are the optic vesicles, and farther back are invaginations of the ectoderm for the internal ear. Two gill clefts and three branchial arches are present; branches of the aorta pass through the latter.

Embryonal Stage. With the formation of the medullary tube and its cephalic enlargements begins the embryonal stage. During the third week the embryo grows rapidly in size and attains a length of about 4 millimeters. The brain increases in size and shows the three primary divisions. The optic and otic vesicles become more prominent. Two more gill clefts and three more gill arches appear, caudal to the ones already formed. The attached area of the yolk sac has diminished. The mouth cavity communicates with the pharynx. By the twenty-first day the limb buds appear. Internally the heart is enlarged and takes the form of an S-shaped tube. From the aorta now arise five pairs of arteries which pass through the five pairs of gill arches joining on the dorsal side of the pharynx into a common dorsal aorta. By the narrowing of the attachment of the yolk sac more of the primitive gut has been folded off, so that now the fore-gut, mid-gut, and hind-gut are to be distinguished. In the fore-gut can already be made out the pharynx with its diverticula, the cesophagus and the stomach. Of the pharyngeal diverticula, there are four pairs of gill pockets, corresponding to the gill clefts on the external surface and separated from the gill clefts by a membrane. From the pharynx has also started the diverticulum for the respiratory tube and lungs. The mid-gut forms the small intestine and portion of the large intestine, and from it have arisen diverticula which give rise to the liver and pancreas. The hind-gut gives rise to the rest of the large intestine and the rectum. By enlargement and growth of the amnion around the embryo until it joins the pedicle has been formed the body cavity. From this later are separated the pleural, pericardial, and peritoneal cavities. The primitive urogenital system has appeared as a ridge along the dorsal wall of the body cavity at either side of the median line in the posterior half of the embryo. This ridge con-

tains the Wolffian duct and tubules and the rudiment of the Müllerian duct. There is no sex differentiation.

Fourth Week. During the fourth week growth is relatively more active than at any other time. The embryo about doubles in length. During the first part of the week the embryo becomes very much flexed, so much so that the head and tail nearly touch. The brain vesicles

Muscle fibres are beginning to differentiate from the cells of these segments, and their ventral ends grow into the primitive abdominal wall formed by the growing around of the amnion. Condensed mesenchyma marks portions of the vertebral column. In the arm bud the mesenchyma is beginning to differentiate into skeletal and premuscle tissue. The Wolffian ridge has increased in size, and the Müllerian duct is now

formed and runs parallel with the Wolffian duct. A diverticulum from the lower end of the Wolffian duct indicates the beginning of the permanent kidney and its duct. On the Wolffian ridge are also seen the first traces of the sexual glands, but not until the fifth week can sex be determined, even by microscopical examinations.

Fifth and Later Weeks. By the middle of the fifth week the embryo is 9 millimeters in length. The amniotic sac is now so much enlarged that it is everywhere in contact with the chorion. A true umbilical cord of some length has developed from the abdominal pedicle attaching the embryo to the chorion as did the pedicle. The head is as large as the rest of the body, due to the rapid growth of the brain. The three primary divisions of the brain are more marked and bent upon each other, and the cerebral hemispheres have begun to grow. The spinal cord is a thick-walled tube. The various cranial and spinal nerves now extend some distance into the body, and the motor nerves reach the premuscle masses of the head and shoulder. The gill clefts and arches are undergoing marked changes. From the first arch the upper and lower jaws are developing. From the first cleft the external auditory canal

FIG. 4. EMBRYO ONE MONTH OLD.

a, a, a, cranial nerves; *a.v.*, auditory vesicle; *b*, bronchus; *c*, cloaca; *h*, hypophysis; *k*, kidney; *l*, liver; *p, p, p*, branchial pockets; *t*, thyroid gland; *w.d.*, Wolffian duct. (After Mall.)

are better developed, as also are the gill clefts and arches, the eyes, ears, and nasal pits. The S-shaped tubular heart with its single cavity is rapidly changing into a complicated four-chambered structure with imperfect partitions. By the end of the fourth week (Fig. 4) the anterior enlarged portion of the head has become bent at right angles to the main axis of the body. From the first gill arch a maxillary process is developing which will ultimately form a portion of the upper jaw; the main portion of the arch will form the lower jaw. The limb buds have increased in size. The arm bud projects from the cervical region, and the leg bud from the lumbar region. The yolk sac is very small, and the amniotic sac is much enlarged. Internally the nerves have begun to grow from the medullary tube or central nervous system into the mesenchyma. Plexuses are forming, but the nerves are not attached to their end organs. There are now 38 primitive segments formed from the mesenchyma lateral to the spinal axis.

and eardrum are forming, and from the pharyngeal portion of the cleft the Eustachian tube and middle ear; while the small bones of the ear arise from the dorsal portion of the first gill arch. From the second arch is forming the hyoid apparatus, and the remaining arches and clefts are beginning to disappear. The arm and leg are enlarged and show two segments. The skeletal system consists of condensed mesenchymal tissue.

By the time the embryo is five weeks old it has attained a length of 11 millimeters. The head is still very large and bent at right angles to the main axis of the body, and the features of the face are forming. The general body musculature is well advanced and has most of its nerve supply. The ribs and the muscles of the thorax and abdomen have grown some distance into the thin membrane which in early stages constitutes the ventral body wall. The limbs are much enlarged and contain a skeletal core of cartilage surrounded by the developing

muscles. Only the fourth pair of the aortic arches now persists entire. The others are modified in various ways to form the larger arteries connected with the aortic arch. The arm keeps about two weeks in advance of the leg in its internal differentiation. The vertebral column and ribs are formed partially in cartilage. The liver has been increasing rapidly in size, and in this embryo, as in the preceding stage, it forms with the heart most of the large projecting abdomen and thorax. The allantois forms a long narrow tube extending from the hind-gut into the umbilical cord as far as the chorion; at a later stage the umbilical portion becomes obliterated, while the portion near the hind-gut enlarges into the bladder.

In an embryo seven weeks old and 20 millimeters long the early fetal features are fairly well marked. The head has now become nearly erect. The fusion of the maxillary and nasal processes is proceeding rapidly to form the upper jaw, and the nasal pits have approached nearer to the median line. The arms and legs are much elongated, show the three segments seen in adults, and fingers and toes are to be distinguished. Every muscle of the body can now be recognized and has also its nerve supply. Most of the skeletal elements are present in cartilage, but portions of the skull are never so represented. The ribs have extended nearly to the mid-ventral line, and the thoracic and abdominal muscles have pushed farther out. By the end of the second month the permanent kidney is fairly well formed, and the Wolffian body, which so far in the life of the embryo has performed the function of an excretory organ, begins to lose its importance. All but the middle portion, which later forms the sexual gland, atrophies. Its duct in the male forms the vas deferens, in the female degenerates; while in the female the Müllerian ducts form the Fallopian tubes and uterus, and in the male degenerate.

By the end of the second month, therefore, most of the organs found in the adult are formed, and the main processes henceforth until birth are the growth and differentiating of these organs. The external form resembles the human form, although the head unduly preponderates. The limbs acquire definite shape, and imperfect nails are present. The external sexual organs become differentiated into male or female. During the fourth month short hairs without pigment appear on the scalp and parts of the body. The eyelids, nostrils, and lips are closed. The anus opens, and the coils of intestines which were in the umbilical cord now lie entirely within the abdominal cavity. The head forms one-fourth of the body. Ossification of many of the bones is well under way. From this time the embryo is called a "fœtus," and its development and characteristics are described under FŒTUS.

EMBRYOLOGY IN PLANTS. The study that deals with the earliest stages of plants. In general the embryo arises from the germination of a spore. In ordinary usage, however, the term "embryo" has been applied to the young plant which is developed within the seed. This embryo is the result of the germination of a fertilized egg, and it is definitely limited by the fact that it passes into a period of rest protected by the seed coats. In the first development of embryology it was thought to be necessary to describe in detail each cell division, especially its plane, from the original segmentation of the egg to the appearance of the growing points of the different regions of the body. Under these circumstances embryology became a very rigid subject, with its categories of "types" and their modifications. Now it is recognized that the development of an embryo varies in response to varying conditions, that there is no rigid sequence in cell divisions, and that the usual uniformity observed is an evidence of uniform conditions rather than of rigid morphological sequence. The present study of embryology is giving scant attention to the sequence of cell divisions, but is concerned chiefly with the organization of the body regions. In other words, it begins where the older embryology stops. This newer phase of the subject, however, is not organized as yet for general presentation. The development of the embryos of various groups of plants given in the following paragraphs, therefore, will be understood as representing the usual early development, which may vary at any stage.

In Mosses. In mosses the fertilized egg rests in the female organ (archegonium), which is at the apex of a leafy stem. This fertilized egg begins to germinate at once, and its first wall, resulting in a two-celled embryo, is at right angles to the long axis of the archegonium. The two cells thus formed proceed upon different lines of development: the lower one produces a descending structure called the "foot," which penetrates into the tissue of the leafy stem and anchors the embryo; the upper cell produces the shoot, which is differentiated into stalk and capsule. In this case, therefore, there is no strict point at which the structure may be regarded as ceasing to be an embryo, the whole development being continuous.

In Ferns. Among the ferns the archegonium in which the fertilized egg occurs is situated upon the underside of the small prostrate sexual plant (prothallium). In ordinary cases the fern embryo is formed in a somewhat different manner from that described for the mosses. The first wall of the egg, resulting in a two-celled embryo, is parallel with the long axis of the

archegonium, the two cells thus formed facing the apex and base of the prothallium. Each of these cells immediately divides, resulting in the so-called "quadrant stage" of the embryo. Each of these quadrant cells is destined to develop a definite body region. The two cells which face the apex of the prothallium develop the stem and leaf structures; those which face the base of the prothallium develop the root and foot structures. The first wall of the fertilized egg, therefore, has had the same general result as the first wall of the egg in the case of mosses; i.e., it has resulted in separating what may be called the root and the shoot structures. In the ferns the development of the young plantlet is continuous, so that the embryo is limited by no special point in time or structure.

In *Spermatophytes*. Among the seed plants the conditions are quite different. The fertilized egg which lies within the embryo sac of the ovule proceeds to germinate at once and to form an embryo of a variable degree of advancement, and then the whole process is checked by the final hardening of the seed coats. On account of this the embryo lies dormant for an indefinite period, and when the seed is said to germinate the embryo renews its activity and escapes. In this way it is convenient definitely to mark the embryo as the plantlet that is developed within the seed. As might be expected, such embryos differ very much in the amount of their development. Some pass into the dormant stage at a very early period in their history, so that they are hardly more than a small indefinite group of cells; others develop several distinct organs and resemble a well-defined plantlet before passing into the dormant stage. Among seed plants, while there is considerable variation in the details of germination, the general sequence is as follows: The fertilized egg develops a transverse wall, and successive transverse divisions result in a linear row of cells, the cell at one end of the row being anchored to the wall of the embryo sac. The cell at the free or deeper end of the row is the one which either exclusively or chiefly enters into the formation of the embryo, the rest of the row forming the so-called "suspensor" (q.v.), which is an organ of the embryo that serves to connect it with the food supply. In any event, this development of the suspensor results in placing the cell which is to develop the embryo more in the centre of the sac, and hence in a position to be better embedded in the nutritive tissue.

The monocotyledons and dicotyledons are fundamentally different in the organization of their embryos. In both groups the root tip is organized at that end of the axis which points towards the micropyle (the opening left by the integument), and for this reason it is the root tip that first emerges from the seed. In the case of the monocotyledons the end of the axis remote from the root tip organizes the single massive seed leaf (cotyledon), while the stem tip arises laterally, just behind the cotyledon. Naturally in such an embryo there can be but a single cotyledon, and this fact has given name to the group. In the dicotyledons this remote end forms the stem tip, while the cotyledons appear as lateral members just behind the stem tip. This prevailing result in two cotyledons, which has suggested the name of the group; but it does not preclude the development of a single cotyledon, or of more than two. For example, his type of embryo belongs to the conifers,

where in many cases the cotyledons form a rosette of several members. The regions of the complete dicotyledonous embryo, which are more easily defined than those of the monocotyledonous embryo, are as follows: The axis beneath the two cotyledons, at the tip of which is the embryonic root structure, has been named the "hypocotyl." This has been variously called "caulicle" and "radicle," one name expressing the idea that it is a little stem and the other that it is a little root. It is, however, so peculiar in its structure and powers that it can hardly be called either a distinct stem or a distinct root, so that it has received a name of its own and may be regarded as an organ of the embryo. At the summit of the hypocotyl the two cotyledons occur, variously arranged with reference to each other and to the hypocotyl in the seed. Between the cotyledons, as if continuing the axis, there is often a minute bud called the "plumule," which, after the escape of the embryo, develops the shoot. For an account of the escape of the embryo, see SEED.

EMBRYOTOMY (from Gk. *ἐμβρυον*, *embryon*, embryo + *τομή*, *tomē*, cut, from *τέμνειν*, *temnein*, to cut). A division of the fetus into fragments, to extract it piecemeal, when the narrowness of the pelvis of the mother, or some other faulty conformation, opposes delivery.

EMBURY, PHILIP (1729-75). The first Methodist minister in America. He was born of German parents at Ballygaran, Ireland, Sept. 21, 1729. He emigrated to America in 1760. In 1766 he organized a "class" in New York and began preaching, at first in his own house on Barrack Street, now Park Place, and in 1767 in the rigging loft on what is now William Street, which has become famous as the cradle of Methodism in the United States. A chapel was built in 1768 on the site of the old John Street Church, partly by Embury's own hands. In 1769 preachers sent out by Wesley arrived in New York, and Embury went to Camden, N. Y., where he worked at his trade of carpentry and preached on Sundays, organizing a church at Ashgrove. This church is still in existence as St. Luke's Methodist Episcopal Church, Albany. He died from an accident, August, 1775. Consult J. Atkinson, *The Beginnings of the Wesleyan Movement in America* (New York, 1896), and Buckley, *History of Methodism*, vol. i (ib., 1898).

EMDEN, *эм'ден*. A city in the Prussian Province of Hanover, situated on an inlet of the Dollart Bay at the mouth of the Ems-Jade Canal and about 75 miles west-northwest of Bremen (Map: Prussia, B 2). It lies low, and its dikes and low-gabled houses give it a quaint Dutch air. It is well built, has spacious and well-paved streets, and is intersected by numerous canals, which are crossed by many bridges. The principal building, and one of the finest public edifices in the whole region, is the sixteenth-century town hall, which contains a library and a curious collection of ancient arms and armor. A large Protestant church, dating from the twelfth century, contains a number of fine monuments. Other interesting buildings are the museum of natural history, the art gallery, the library, and the old barracks. It has schools for the teaching of trade, industry, navigation, and telegraphy; also a deaf and dumb institute. Emden is a cable centre of lines from Great Britain, Spain, and North America. The chief industry is shipbuilding, but there are also ex-

tensive manufactures of machinery, dairying instruments, cable, rope, cement, pasteboard, paper, wire, tobacco, soap, mustard, and basketware. The herring fishery is also important. Emden is connected with Wilhelmshaven by the Ems-Jade Canal. Pop., 1900, 16,453; 1910, 24,038. Emden was known as early as the tenth century. In 1433 it came under the dominion of Hamburg. In 1595 it was raised to the rank of a free Imperial city, and its commerce at that time was extensive. It was made a free port in 1751, was occupied by Holland in 1806, and with the whole of East Friesland was incorporated with the Kingdom of Hanover in 1815 and in 1866 was united to Prussia.

EMELÉ, á-mà-lá', WILHELM (1830-1905). A German battle painter. He was born at Buchen, Baden, and, after studying in Munich under Dietz, in Antwerp, and in Paris, he settled in Vienna (1861), where he attained great popularity as a painter of equestrian portraits and hunting scenes. His "Battle at the Neckar Bridge in Heidelberg" was bought by the Austrian Emperor, and his "Cavalry Encounter near . . ." won the first medal at the . . . in 1873. Afterward he resided successively in Munich, Berlin, and Karlsruhe. Among his other works are "Attack of French Cuirassiers at Waterloo" (1867) and the "Battle of Nuits, December 18, 1870," in the Karlsruhe Gallery. His paintings show exact knowledge of military detail and are spirited in conception and good in color.

EMERALD (OE. *emeraud*, OF. *esmeraude*, Fr. *émeraude*, Sp. Port. *esmeralda*, It. *smeraldo*, Lat. *smaragdus*, from Gk. *σμάραγδος*, *smaragdōs*, *μάραγδος*, *maragdōs*, emerald, Skt. *marakata*, emerald). A green-gem variety of the mineral beryl. It was known to the ancients, who valued it for its supposed occult properties and its marvelous power of healing all diseases of the eye as well as for its beauty. Pliny tells of a life-size figure of a lion in Cyprus with large emerald eyes that were so brilliant when the sun shone upon them that fish were frightened away by them. The Emperor Nero had an eyeglass of emerald through which he viewed the sports of the arena. Cortés brought from Peru five emeralds of remarkable beauty and curious design, which are described as marvels of the lapidary's skill—one having been cut into a rose, another a horn, a third a fish with golden eyes, a fourth a bell with a pearl for a clapper, and a fifth a tiny cup. The emerald ring taken from the tomb of Charlemagne, which was used by him as a talisman, was worn by Napoleon on the battlefields of Austerlitz and Wagram and was given by him afterward to Queen Hortense.

In composition the emerald is essentially a glucinum-aluminum silicate, with small quantities of the oxides of calcium, iron, and chromium, the brilliant green color of the gem being attributed to the last-named constituent, though according to some authors it is due to traces of organic matter. The hardness of the emerald is 7.5 to 8, and its specific gravity is 2.5 to 2.7. Originally emeralds came from the Orient and especially from Upper Egypt, where mines are again worked. They are also found near Tokovaya in Siberia, where very large specimens have been obtained. Many of the gem varieties are from the mines of Muso in the United States of Colombia, and from Emmaville, New South Wales. In the United States emeralds have been found in Alexander and Mitchell counties,

N. C. Flawless specimens of emerald are exceedingly rare and command a price almost equal to that of the diamond, and the expression "an emerald without a flaw" signifies unattainable perfection. *Brazilian emerald* is a green variety of tourmaline. *Lithia emerald* is the emerald-green spodumene, or hiddenite (q.v.). *Oriental emerald* is the green variety of sapphire, or corundum. *Uralian emerald* is the green variety of andradite, or demantoid. See GEMS.

EMERALD COPPER. See DIOPTASE.

EMERALD ISLE. A figurative name given to Ireland (q.v.) on account of the richness of its verdure. It was first used by Dr. Drennan (1754-1820) in his poem entitled "Erin."

EMERALD WEDDING. See WEDDING ANNIVERSARIES.

EMERGENCE (from Lat. *emergere*, to emerge, from *e*, out + *mergere*, to plunge). A plant outgrowth, technically distinguished from a trichome or hair by the fact that it involves the cortex as well as the epidermis. It is not always easy to detect the differences between a trichome and an emergence, so that in ordinary usage the two are continually confused. In fact, no hard and fast line can be drawn between the two. In general, an emergence may be regarded as a structure of lower morphological value than the stem or leaf or root upon which it may be borne, and of higher morphological value than the trichome or hair which arises only from the epidermal tissue. Emergences include not merely such outgrowths as appear to have no definite function, as in the warts, prickles, etc., but they are sometimes pieces of a definite physiological apparatus. For example, the remarkable tentacles of *Drosera*, which are often called glandular hairs, are emergences; the ligules of leaves of grasses, *Sclaginella*, and *Isoetes* are emergences; as are also the cupules of certain liverworts, as *Marchantia*. Perhaps also the suckers or haustoria of such parasitic plants as dodder, mistletoe, etc., are to be regarded as emergences.

The use of such terms as emergence and trichome, as representing rigid morphological categories, has disappeared. Whether a given structure is an emergence or a trichome is of no significance. The significance of any structure is its function, so that structures are grouped now on the basis of their work, without reference to the origin of the cells that enter into them. See the titles of the various structures referred to; also TRICHOME.

EMERITUS (Lat., having served one's time of service). A term which designates certain officials, generally collegiate or pastoral, who have retired from active service by reason of age or illness and retain an honorary position and title corresponding to that held when in active service, as "professor emeritus," "pastor emeritus."

EMERSION (from Lat. *emergere*, to emerge). The reappearance of one heavenly body from behind another, after an eclipse or occultation. The immersions and emersions of Jupiter's satellites are particularly useful for finding the longitude of places, when it is impossible to carry out more accurate determinations with the aid of the electric telegraph.

EMERSON. A frontier town and the capital of Provencher Co., Manitoba, Canada, 60 miles south of Winnipeg (Map: Manitoba, F 4), on the Canadian-Northern and the Canadian

Pacific railroads, and on the right bank of the Red River. The industries include a cement-block plant, dairying and ranching, and lumbering. The United States is represented by a consular agent. Pop., 1901, 840; 1911, 1043.

EMERSON, ALFRED (1859-). An American archaeologist, appointed associate professor of classical archaeology at Cornell University in 1891. He was born at Greencastle, Pa., and was educated in Germany and at the Johns Hopkins University. Professor Emerson's publications include *Dissertatio de Hercule Homericco* (1881). From 1891 he was for some years a contributing editor of the *American Journal of Archaeology*.

EMERSON, BENJAMIN KENDALL (1843-). An American geologist, born at Nashua, N. H. He graduated in 1865 at Amherst College, where, after further study at Berlin and Göttingen (Ph.D., 1870), he became instructor in geology and professor of mineralogy and geology (1872). For some years after 1878 he occupied in addition the corresponding chair at Smith College. He was assistant geologist in 1890-96, and thereafter geologist, of the United States Geological Survey, for which he prepared a number of valuable geological maps of Massachusetts. He was vice president of the American Association for the Advancement of Science in 1896, vice president of the International Geological Congress at St. Petersburg in 1897, and president of the Geological Society of America in 1899-1900.

EMERSON, GEORGE BARRELL (1797-1881). An American educator, born at Kennebunk, Me. He graduated at Harvard, where he was tutor in mathematics and natural philosophy in 1819-21. He was a popular teacher in Boston for many years and served as president of the Boston Society of Natural History and as chairman of the commission for the zoological and botanical survey of the State. He wrote: *Report on the Trees and Shrubs Growing Naturally in the Forests of Massachusetts* (1846; 5th ed., 1894); *A Manual of Agriculture*, with C. L. Flint (1861; rev. ed., 1885); *Reminiscences of an Old Teacher* (1878).

EMERSON, OLIVER FARRAR (1860-). An American philologist, born at Traer, Iowa. In 1882 he graduated from Iowa State College, of whose "Academy" he was principal in 1885-88, and in 1891 he gained the Ph.D. at Cornell University, where, between 1888 and 1896, he was fellow, instructor, and assistant professor of rhetoric and English philology. From 1882 to 1885 he had been superintendent of public schools at Grinnell and Muscatine, Iowa. In 1896 he became professor of English at Western Reserve University. He was president of the American Dialect Society in 1905. He edited *Memoirs of the Life and Writings of Edward Gibbon* (1898), *Johnson's Rasselas* (1905), and *Poems of Chaucer* (1911), and, besides contributing to philological journals, is author of *History of the English Language* (1894); *A Brief History of the English Language* (1896); *Middle English Reader* (1905); *Outline History of the English Language* (1906).

EMERSON, RALPH WALDO (1803-82). A famous American poet and essayist, born in Boston, Mass., May 25, 1803. His parents were the Rev. William Emerson and Ruth Haskins, and from them he received the training that the better class of New England parents

bestowed upon their children. His boyhood was passed mainly in Boston. At the age of 20 he was graduated from Harvard College and taught school for a time; then, like a large number of the educated youth of New England at that time, he studied for the ministry. He was ordained March 11, 1829, and became the colleague of Rev. Henry Ware, pastor of the Second Church (Unitarian) of Boston. On September 30 of the same year he married Miss Ellen Louisa Tucker, who died Feb. 8, 1832. Shortly after his association with Ware the latter retired from active service, and Emerson became pastor of the church, one of the foremost in New England. On Sept. 9, 1832, however, he resigned his office, saying, in his farewell sermon, that he had ceased to regard the Lord's Supper as a necessary rite and that he was unwilling longer to administer it. Up to that time he had been known as an able, earnest, and pleasing preacher with tendencies towards radical theology; after one or two attempts to join himself with other parishes, he now entered upon his lifelong career as lecturer and essayist.

In the fall of 1833 he took his first trip to Europe, where he visited Sicily, Italy, France, and England, and met several well-known Englishmen, among them Landor and Carlyle. On Sept. 14, 1835, he married Miss Lidian Jackson. The winters of 1835, 1836, and 1837 were marked by series of lectures, delivered in Boston, on "English Literature," "The Philosophy of History," and "Human Culture." His more elaborated statement of belief, however, is to be found in his first published book, *Nature* (1836), given out anonymously, but soon attributed to him. The volume had a small sale and received almost no popular notice, but it was important as an exposition of the basis of Emerson's philosophy and was accepted by such men as Carlyle as worthy doctrine. Briefly it was a praising of the idealist view of human life, as opposed to the materialist, then common in England and America, and the Calvinist dogma, then still pervasive in New England, and he made the essay a plea for individual freedom. The tendency of criticism to-day is to regard *Nature* as the most poetic and the most original of Emerson's writings, containing in the germ all his later essays and poems. The following year, on August 31, Emerson delivered the Phi Beta Kappa oration at Harvard College on "The American Scholar." This was called by Holmes the "intellectual declaration of independence" for America. Containing, in general, the lofty ethical principles of the author, it is, in particular, a sober and earnest exhortation of his hearers to lead their lives with thoughtfulness, austerity, and self-trust, not leaning for support on the traditions and precepts of the past, but cleaving a way independently in the present. The following year was also notable for proclamations of emancipation. On July 15, 1838, he delivered an address before the students of the Divinity School at Cambridge, expressing his belief in the validity of individual thinking in religious affairs, and on the 24th of the same month he set forth the same general point of view at Dartmouth College, New Hampshire, in a lecture called "Literary Ethics." The first of these incited a warm and widespread controversy, in which Emerson, as usual, took no active part. Throughout his life he never did more than

RALPH WALDO EMERSON

state his views in his own vigorous and winning language, content to let others carry on the discussion which he might have aroused, or body forth in some practical form the impulse which he had given them.

In 1841 the first of his *Essays* appeared. The volume contained several of the papers which have remained of all his work the most popular. It comprised "History," "Self-Reliance," "Compensation," "Spiritual Laws," "Love," "Friendship," "Prudence," "Heroism," "The Over-Soul," "Circles," "Intellect," and "Art." The second series of *Essays* appeared in 1844, containing such titles as "The Poet," "Manners," "Character." In the interval between these two volumes Emerson had done much writing for the *Dial*, the organ of New England idealism, or Transcendentalism as it was called. The paper was started in 1840, with Margaret Fuller as editor. Emerson himself succeeded her and remained editor till the collapse of the enterprise in 1844. With the other and better-known experiment of the Transcendentalists, the Brook Farm (q.v.) Community, Emerson had nothing to do. He had found on inquiry that the soil of Brook Farm was poor, and he disapproved of an adventure so inexpertly undertaken. In 1847 appeared the first volume of Emerson's poems, many of which had been published in the *Dial* during its brief existence. In the same year he wrote the editor's address for the newly founded *Massachusetts Quarterly Review*, but did no further writing for it. In October he set sail for Europe for the second time. He delivered in England a series of lectures, some of which he gathered together in a volume entitled *Representative Men* (1850). The subject suggests Carlyle's *Heroes and Hero-Worship* of 10 years before; but the treatment of the subjects and the manner of approaching them are different. With Carlyle, the hero, be it in war or in letters, is the man who molds the way of the world; with Emerson the representative man is so called simply because he stands for an ideal of individual integrity—a character whence springs his worth. The journey to Europe also resulted in 1856 in a brilliant book of travel, *English Traits*. In 1860 appeared *The Conduct of Life*, the first of his books to enjoy immediate popularity, a volume of essays on such subjects as "Power," "Wealth," "Fate," and "Culture." This was followed in 1867 by a collection of poems, which had previously been published in the *Dial* and the *Atlantic Monthly*, entitled *May Day and Other Pieces*, and in 1870 by another volume of ethical essays, *Society and Solitude*. During the winters of 1868–70 Emerson delivered a series of lectures at Harvard College on the *Natural History of Intellect*, which were posthumously published (1893). He made his third and last voyage to Europe in 1872. From about this time his memory began to show signs of giving way, and, though he retained to the end of his life his command of his general ethical principles, his work after 1875 was fragmentary and scattering. In 1874 he made a collection of favorite poems, which he called *Parnassus*, and the following year his last volume of essays, *Letters and Social Aims*, appeared. A revised edition of his poems followed in 1878, and the same year were published a lecture on the "Sovereignty of Ethics" and one on the "Fortunes of the Republic." His death, which came after

a short illness, occurred at Concord, Mass., April 27, 1882.

Emerson is described as tall and slender. He was nearly 6 feet in height and weighed about 140 pounds. He was not erect in carriage. His head was rather small in dimension, long and narrow, but lofty and symmetrical. "His face," says Holmes, "was thin, his nose somewhat accipitrine, casting a broad shadow; his mouth rather wide, well formed and well closed, carrying a question and an assertion in its finely finished curves; the lower lip a little prominent, the chin shapely and firm. His whole look was irradiated by an ever-active inquiring intelligence. His manner was noble and gracious." His personal habits were of the simplest sort, but were in no wise ascetic. He is said to have been somewhat oppressed by a feeling, not uncommon among New Englanders of the more refined sort, of physical insufficiency; and this trait may account for the fact that he rarely gave himself to active measures, but chose to live the contemplative life.

Emerson takes rank among the foremost writers of his time. All his prose, with the possible exception of one or two chapters in *English Traits* and a few biographical sketches, may be strictly called essays. They represent a point of view of singular unity and persistence, and the chronology is really unimportant. Possibly the addresses printed in the volume called *Nature*, together with that tract, all of which were written before 1845, represent a slightly more enthusiastic and zealous spirit than the later essays and are rather more specific in subject. But, in the main, all the essays set forth a constant and enthusiastic belief in the value of individuality and the need of every man's planting himself in the ground of his own consciousness and natural affection. Being himself a man of many intuitions and of wonderful vigor in them, he is to be regarded as a philosopher rather than as a philosopher. He sought to construct no system, but stood for a constant idealistic impulse.

Emerson's poetry is written from much the same point of view as his prose. While his contemporaries and friends among American poets were expressing themselves variously, as Poe in the search for beauty, or Longfellow in the phrasing of generous truisms and romance, or Whittier in his antislavery verse, or Holmes in his graceful occasional way, Emerson was uttering his feeling for the innate morality of the universe. The number of his poems is not large, for he wrote only when the mood prompted him and not systematically. Few of his poems are long, but one is narrative, and almost all may be termed philosophical and reflective. They are by no means so popular as those of Longfellow or of Whittier; but among them are to be found some of the best poems that America has produced. Among the best known are: "The Sphinx," "The Problem," "Hamatreya," "The Rhodora," "The Humblebee," "The Snow-storm," "Woodnotes," the "Threnody," in commemoration of the death of his young son, the "Concord Hymn," "Brahma," "Voluntaries," "Terminus," and the quatrain "Sacrifice."

Emerson has been the subject of much criticism. That of an adverse sort censures him for relying chiefly or altogether on his intuitive consciousness instead of submitting his generalizations to the test of reason. Though gifted, to a degree very unusual among men, with a

genius for piercing appearances, he seldom or never took . . . say the rationalists, to analyze these vivid impressions with a view to . . . their verity. The consequence is : . . . some of his work is fresh and wholesome in its truth-bearing qualities, much of it is obscure and unsubstantiated in the common experience of mankind. Another criticism somewhat akin to this is directed at his frequent superficiality, born of the same failure to verify statements by patient investigation. In consequence of this trait his work is very uneven, disjointed, and formless. It is an agglomeration of detached sentences and epigrams, rather than a reasonable and consecutive . . . uth. Finally, it is charged . . . on his immediate followers was to cultivate a frequently epigrammatic and obscure manner of uttering platitudes and shallow thought and that in the main he has retarded in America the growth of reasonable thinking processes. On the other hand, even his severest critics would admit that his influence has largely been wholesome. That influence has certainly been vast; no other American man of letters probably has been so potent a source of inspiration to his fellows, nor seems more likely to contribute permanently to European thought. His influence upon Maeterlinck and Bergson in France, and upon Nietzsche in Germany, of itself gives him international importance. Coming at a time when the general tendency in America was towards a belief in material happiness, he taught that a man has also a spring of joy and hope in his inner consciousness. He stimulated men to a better faith in themselves, induced them to rely less on number, masses, and externals. Except in a few specific counsels, as about the reading of books, he rarely uttered a particular dogma, but stood generally for a large and dignified attitude towards life. He was a firm believer in the inner goodness of his country and of his fellow citizens.

Emerson's manner is unfailingly characteristic and original. He uses homely, simple language, racy of the soil of New England, very specific in its wealth of imagery, but never crude. His writing is almost always lively, but never fails to betray the calm and dignified spirit of the writer. It is often disjointed and often uneven, epigrammatic, and choppy, but not infrequently contains a passage of great power and beauty. Many of his sayings, as "Beauty is its own excuse for being," and "A foolish consistency is the hobgoblin of little minds," are household phrases, and of longer passages few anywhere are more forcible than such as that on the use of books, in "The American Scholar," or the closing paragraphs of his "Lecture on the Times." The one-hundredth anniversary of Emerson's birth was celebrated all over the United States and in England.

Bibliography. The standard text of Emerson is published by Houghton Mifflin Co.: the most convenient edition is the Centenary (12 vols., 1903). The *Journals* are published by the same firm in 10 vols. (1909-14). Consult also: *Correspondence of Emerson and Carlyle*, ed. C. E. Norton (Boston, 1886); *Letters from Ralph Waldo Emerson to a Friend*, ed. C. E. Norton (ib., 1899); G. W. Cooke, *Bibliography of Ralph Waldo Emerson* (ib., 1904). The chief source of facts for Emerson's life is Cabot, *A Memoir*

of Ralph Waldo Emerson (Boston, 1887). Consult also: Joel Benton, *Emerson as a Poet* (New York, 1883); Holmes, in the *American Men of Letters Series* (Boston, 1885); Garnett, in the *Great Writers Series* (London, 1888); and Woodberry, in the *English Men of Letters Series* (New York, 1904); Cooke, *Emerson: His Life, Writings, and Philosophy* (Boston, 1882). Sketches of personal traits may be found in Higginson, *Contemporaries* (Boston, 1899); Thayer, *A Western Journey with Emerson* (ib., 1884); Conway, *Emerson at Home and Abroad* (ib., 1882); Howells, *Literary Friends and Acquaintance* (New York, 1900). Good critical essays are those of Matthew Arnold in *Discourses in America* (London, 1885); John Morley, in *Critical Miscellanies*, vol. i (ib., 1893); Eliot, *Emerson as Seer* (Boston, 1904). Grimm, *New Essays* (Berlin, 1865); Wendell, *A Literary History of America* (New York, 1900); *Correspondence between Emerson and Grimm* (1903); Albee, *Reminiscences of Emerson* (New York, 1903); Cary, *Emerson, Poet and Thinker* (ib., 1904); Sanborn, *Personality of Emerson* (ib., 1904); M. Dugard, *Ralph Waldo Emerson: Sa vie et son œuvre* (Paris, 1907); H. C. Goddard, *Studies in New England Transcendentalism* (New York, 1907); I. S. Harrison, *Teachers of Emerson* (ib., 1910); Maurice Maeterlinck, *Emerson and other Essays* (trans., ib., 1912).

EM'ERTON, EPHRAIM (1851-). An American historian. He was born in Salem, Mass., and studied at Harvard (1871) and Leipzig . . . 1876 he became a tutor in history at Harvard and in 1882 was elected Winn professor of ecclesiastical history. His principal works on the Middle Ages and the . . . of the Reformation, *An Introduction . . . of the Middle Ages, 375-814* (1888), *Medieval Europe, 814-1300* (1894), and *Desiderius Erasmus*, in "Heroes of the Reformation" (1899), are of great value. With Diesterweg, H. B. Adams, and others he wrote *Methods of Teaching History* (1883).

EMERTON, JAMES H. (1847-). An American naturalist and illustrator, born at Salem, Mass. He illustrated Packard's *Guide to the Study of Insects*, Scudder's *Butterflies in North America*, A. E. Verrill's papers in *Reports of the United States Fish Commission* (1874-84), and C. S. Minot's *Embryology*. He also constructed zoölogical and anatomical models for museums at Cambridge, New Haven, New York, Philadelphia, and Washington. Besides seven papers in the *Transactions of the Connecticut Academy* on "The New England Spiders," he is author of *The Structure and Habits of Spiders* (1878) and *Common Spiders of the United States* (1902).

EM'ERY (formerly *emeril*, from OF. *emeril*, Sp., Portug. *esmeril*, It. *smiriglio*, from Gk. *σμίρις*, *smýris*, *culpis*, *smiris*, *emery*). A variety of corundum (q.v.), or of the same mineral species of which corundum and sapphire (with Oriental ruby, etc.) are also varieties. It agrees with them very perfectly in hardness and specific gravity, but is dull, opaque, and not crystallized, sometimes of a grayish black and sometimes of a blue color. It contains chiefly alumina and oxide of iron, but less of the former than does either corundum or sapphire. Margarite, garnet, spinel, and other minerals may be associ-

ated with the corundum. Emery occurs both massive and disseminated; although very compact, it has a somewhat granular structure. It is found at a number of different localities. In Asia Minor, which is an important commercial source, it occurs as lumps or masses in crystalline limestone, or in the residual clay from the same. Most of the emery used in America comes from Turkey, but in the United States it is known to occur at Chester, Mass., and Peekskill, N. Y., while corundum in deposits of economic value is found in North Carolina and Georgia. The Chester emery forms lenses in a hornblende schist, while the Peekskill material is found as masses in gabbro, an igneous rock, from which it has segregated during the process of cooling and crystallization.

It is prepared for use by first breaking it into pieces about the size of a hen's egg, then crushing these to powder by stamps. It is then sifted to various degrees of fineness, which are numbered according to the meshes of the sieve. Plate-glass manufacturers and others separate emery powder into different degrees of fineness by the method of elutriation. A number of copper cylinders of graduated capacities are placed in a row and filled with water; the emery, churned up with an abundance of water, is admitted by a pipe into the smallest; it then passes to the next in size and finally flows from the largest; and thus, as a given quantity of water with emery suspended in it passes in equal times through vessels of varying capacities, the amount of agitation will obviously be greatest in the smallest vessel, least in the largest, and in like proportion with the intermediate; the largest particles therefore sink in the smallest vessel, and so on till only the very finest will reach the largest vessel. In this manner any number of gradations of fineness may be obtained, according to the number of sizes of the vessels. Elutriation in oil or gum water is sometimes used on a smaller scale, the emery being stirred up in the liquid, and portions poured off at different intervals of time, the finest being of course the last to settle. The use of the oil or gum is to make the subsidence take place more slowly.

Emery thus prepared is used for a great many important purposes in the arts. As it is next in hardness to diamond dust and crystalline corundum, the lapidary uses it for cutting and polishing many kinds of stone. Glass stoppers of all kinds are ground into their fittings, with it. Plate glass is ground flat by its means; it is also used in glass cutting and in grinding some kinds of metallic fittings. When employed for the polishing of metals, it has to be spread on some kind of surface to form a sort of fine file. Emery paper, emery cloth, emery sticks, emery cake, and emery stone are various contrivances for such purposes. Emery paper is made by sifting emery over paper which has been covered with a coating of glue. It is used either by wrapping it round a fine file or a stick, or in the hand, according to the form of the work. Emery cloth is made like emery paper, with coarse cloth substituted for the paper. The emery does not adhere so well to this as to paper, and it is therefore not used by metal workers, who work emery paper till smooth with wear, but is chiefly used for purposes where the hand alone is used and paper would tear. Emery sticks are used for the same purposes as emery paper wrapped round files; they are made of

wood sticks shaped like files, then glued over, and dipped once or twice in a heap of emery. Emery stone is a kind of earthenware mixed with emery, formed by pressing a mixture of clay and emery into suitable molds and then firing, like common earthenware. It is molded into wheels, laps, etc. Its hardness and cutting power are very considerable. Emery wheels are most efficient; they vary in diameter from 1 to 36 inches and are revolved at a high velocity. Consult Merrill, *Non-Metallic Minerals* (New York, 1910), and Pratt, *North Carolina Geological Survey*, vol. i (1905). See ABRASIVES.

EMERY, HENRY CROSBY (1872-). An American economist, born at Ellsworth, Me. He graduated from Bowdoin College in 1892 and studied at Harvard (A.M., 1893), Columbia (Ph.D., 1896), and Berlin universities. Between 1894 and 1900 he was instructor and professor of political economy at Bowdoin and from 1900 to 1909 professor of political economy at Yale. In the latter year he became chairman of the United States Tariff Board, but in 1913 he returned to his position at Yale. He is author of "Speculation on the Stock and Produce Exchanges of the United States," in *Columbia University Studies* (1896); *The Tariff Board and its Work* (1910); *The Work of the Tariff Board in Connection with the Cotton Industry* (1911); *Politician, Party, and People* (1913); *Some Economic Aspects of War* (1914).

EMERY, STEPHEN ALBERT (1841-91). An American musician. He was born at Paris, Me., and studied at Leipzig, where he had such distinguished teachers as Richter, Hauptmann, and Plaidy. After further tuition under Spindler at Dresden he returned to Portland and was shortly afterward appointed instructor at the New England Conservatory in Boston. Here he remained for three years and upon the establishment of the College of Music of Boston University was made harmony and counterpoint at His works comprise pianoforte compositions, songs, string quartets, part songs, and two textbooks respectively on pianoforte playing and on *The Elements of Harmony*. The latter is regarded as a standard work.

EMERYVILLE. A city in Alameda Co., Cal., near Oakland, on San Francisco Bay, and on the Atchison, Topeka, and Santa Fe Railroad. It contains extensive stockyards and packing houses, ironworks, railroad yards, oil refineries, fertilizer plants, paint, rubber, and cracker factories, etc. A noteworthy feature is Shell Mound Park, which contains an old Indian mound. Pop., 1900, 1016; 1910, 2613.

EMESA. See HOMS.

EMETIC (Lat. *emeticus*, Gk. *ἐμετικός*, *emetikos*, emetic, from *ἐμειν*, *emein*, to vomit). Medicine given for the purpose of producing vomiting (q.v.). Emetics are given when it is desired to relieve the stomach of some noxious or indigestible substance, as a poison, or excess of food, or some special article of diet which has disagreed. In some diseases of the respiratory organs emetics are given as a quick and safe method of removing accumulated mucus from the air passages; and in croup (q.v.) their action is especially favorable, being often followed by expectoration and a rapid improvement in the suffocative symptoms. There are two classes of emetics: (1) local irritants to the stomach, as mustard; (2) emetics acting on the vomiting centre in the brain, as ipecacuanha,

apomorphia, and tartar emetic. The former are safer; but ipecacuanha is well borne by children with croup. Emetics are to be given with great caution in all very depressed states of the system, as their primary action is to produce nausea (q.v.), which is attended always with more or less diminution of the vital power and often with great depression of the heart's action, amounting to syncope or fainting.

EMETIC MUSHROOM. See FUNGI, EDIBLE AND POISONOUS.

EMETINE (from Lat. *emeticus*, emetic), $C_{30}H_{40}NO_8$. An alkaloid which forms the active principle of ipecacuanha root. It is a yellowish-white powder, which is slightly soluble in cold water, but dissolves readily in alcohol. When taken internally, it exhibits violent emetic properties. See IPECACUANHA; ALKALOIDS.

EMEU. See EMU.

EMIGRATION (Lat. *emigratio*, removal from a place, from *emigrare*, to emigrate, from *e*, out + *migrare*, to depart). In the broadest sense emigration denotes the transfer of residence from one place to another. But so broad a definition includes many phenomena, such as the movement from rural districts to the cities or the settling of the West by pioneers from the Atlantic States, which are not commonly designated as emigration. To be an emigrant usually implies that a person leaves his own state and places himself under the jurisdiction of a foreign power, that his destination is widely distant from the mother country, and that he is one of many who are doing the same thing. Immigration is obviously the same thing as emigration, however we define the latter, viewed from the standpoint of the country which receives persons from other lands.

History. The movement of tribes and races, some account of which will be found in the article MIGRATIONS, is one of the chief features of history from the earliest times. On the other hand emigration is a comparatively modern phenomenon; it is a movement of individuals rather than tribes and communities, and while it may assume vast proportions, the initiative proceeds from individuals. The history of emigration in this sense really begins with the discovery of America, particularly with the establishment of English colonies on the North American continent. Though the Spanish power was planted in South America and about the Gulf of Mexico much earlier, the Spanish administration was monopolistic in the extreme and did not promote emigration to the New World. As all foreigners were excluded from the Spanish colonies, and no Spaniards permitted to betake themselves thither without special permission of the crown, it will be understood that no considerable stream of immigrants flowed into them. Nor were the French more successful. As they copied in the New World the feudal privileges and inequalities of the Old, the French colonies offered no refuge to the oppressed. In the period of French rule in Canada France indeed poured forth or drove forth some of the best elements of the nation in considerable numbers, but these were Huguenots, to whom Canada was barred.

In marked contrast with these colonies were the English settlements in the New World. Widely scattered, they offered to the Pilgrim in New England, the Quaker in Pennsylvania, and the Catholic in Maryland freedom from the restrictions of the Old World, while most of the colonies offered complete religious freedom to

all comers. It was therefore to the North American continent that the stream of emigration which had its principal sources in England and Germany flowed. During the brief period of Dutch rule on the Hudson there was some influx of Netherlanders, with whom were associated some Huguenot refugees, while the Swedish settlements on the Delaware were too ephemeral to leave many traces behind them in the population of the region. From central, eastern, and southern Europe there was no emigration in the eighteenth century; nor did it assume considerable proportions until the close of the nineteenth century. The numbers of such emigrants were very small compared with those of modern times; precise records do not exist, but it may be recalled that in 1800, after at least a century and a half of occupation, the United States had a population of 5,308,483, and this fact may be contrasted with the immigration record for the 10 years 1881 to 1890 of 5,246,616 persons, or nearly 5 millions in the 5 years 1905-09.

Modern emigration begins in the nineteenth century, though its earlier years showed no marked increase on the shifting population during the preceding century, as is evidenced by the paucity of records. It was not until 1820 that the first statistics on the subject, viz., those of immigration into the United States, were established, while until 1840 only 742,564 arrivals were recorded. In the meantime Australia had been opened up for settlement, but before the gold discoveries (1850) it had not attained a population of half a million souls. The potato famine in Ireland, the economic distress of Europe generally in the period of 1845-50, and the discovery of gold in California and Australia stimulated an emigration far in excess of anything which had previously occurred. While the number fell off somewhat after 1860, it rose again after 1870 until it reached the highest point of the century in the early eighties. Until the close of the nineties it remained almost stationary. In the first decade of the twentieth century the volume of emigration increased steadily from 487,918 in the fiscal year 1901 to 1,285,349 in 1907. In 1908 the volume decreased to 782,870, increasing again to 1,041,570 in 1910. In the fiscal year 1913, 1,197,892 persons emigrated to the United States.

Difficulty of Measurement. Precise figures cannot be given, as the records of the ports of departure as well as those of arrival are not always to be had. From a statistical standpoint there are many obstacles to a perfectly accurate record, the chief being that of double counting. Emigrants return to their native land and again emigrate, which causes double counting at the ports of departure; while emigrants pass from one country into another, particularly from Canada to the United States, and this, together with the return of persons who have been in the country before, causes double counting at the points of arrival. These difficulties, which prevent perfectly exact measurements, such as the calculation of an emigration rate for comparison with other phenomena of the population movement, do not impeach the testimony of all available records as to the general growth of emigration. The emigration figures, so far as they are recorded in the European countries, are based upon such diverse elements that careful writers abstain from the attempt to make a total. Almost equally unsatisfactory

for comparative purposes are the records of the countries which receive immigrants. Some notion of the volume of emigration from Europe can be gained from the fact that from 1820 to 1913 the records of the United States show 30,982,114 arrivals. Other regions received comparatively few immigrants until recent years. In 1870 the arrivals in the United States (387,203) far exceeded those of Canada, Brazil, Argentina, Uruguay, and Australia combined, which according to the records of those countries amounted to 108,772 persons, while in 1890 the arrivals in the United States (455,302) were less than those of the five regions above named (546,934). For later years figures are not available, as Canada has discontinued its statistics of immigration; but it may be stated in round numbers that from one million to a million and a half of persons leave Europe annually for foreign lands, about two-thirds of this number coming to the United States.

Causes. No attempt to summarize the causes of emigration in a single phrase can be successful. They are as numerous as the motives which determine conduct. At one time it is the spirit of adventure which calls men forth to seek their fortunes in the unknown. This is peculiarly the case with the gold seekers, whether they followed the Spanish arms to the conquest of Mexico and Peru, or flocked to the mines of California and of Australia, or in our own day bear the hardships of an arctic climate in the Klondike and at Nome. Religious oppression has been a powerful element in causing emigration, as illustrated in our own early history, and to-day in the influx of Russian and Rumanian Jews. Crop failures, like the potato famine in Ireland, and industrial depression at home, are potent factors in determining men to emigrate. The hope of economic betterment, the attraction of cheap land, and the prospect of becoming landowners, the solicitation and representations of friends or relatives who have preceded them—in short, an infinite variety of circumstances may have a deciding influence.

The Loss by Emigration. While emigration may usually be assumed to imply a loss of population, opinion is by no means unanimous that such a loss is an evil. Increasing population may or may not be a national gain. In certain regions there can be no doubt that increase tends to overpopulation, but this cannot be asserted of Europe generally. It is, however, pointed out that emigrants are, as a rule, grown men in the active years of life. In fact, of the arrivals in the United States in 1910-11, 80.9 per cent were adult males between the ages of 14 and 45, while in the population at large there were in 1910 only 50.8 per cent between the ages of 14 and 45. Emigration means a loss of able-bodied workers. How great is the loss? Various attempts have been made to estimate this. One method, that of the celebrated German statistician Engel, reckons the value of an emigrant by the cost of his education and rearing. Other writers insist that his value should be reckoned by his productive capacity, and claim that either the annual income of a laboring man, or at least the excess of his production over his personal consumption, should be taken as a basis for calculating the capital which such income represents. Results will vary according to circumstances and methods of calculation, but they vary from a capitalized value of \$200 to \$2000 per head; which with an emigration of

100,000 persons would mean an annual loss of \$20,000,000 to \$200,000,000. Considerable as these figures are, they shrink into insignificance when compared with the national wealth of Austria-Hungary, or even of Italy or Russia, the only countries which furnish an annual emigration of 100,000 persons. Moreover, it is not universally conceded that these calculations are right in principle, that men as such have a value to the community which represents a capital sum.

Still, if emigration is regarded as a positive loss, it must, on the other hand, be granted that it has compensation in helping build up new markets for the mother country. Further, returning emigrants are likely to bring with them a considerable amount of capital, and, what is more important, new methods of work and new standards of consumption, that react powerfully upon the economic and social life of their native communities. In short, the conditions which surround emigration are so complex that any general rule of its value or harmfulness to the mother country must be so guarded as to be practically valueless.

Relation of the Government to Emigration. The attitude of the state towards emigration has been influenced not so much by economic considerations as by political and sentimental motives. It has ranged from positive encouragement to absolute indifference and positive opposition. The attitude of governments has been greatly influenced by the possession of colonies or by their absence. Whenever the state has had distant colonies, it has sought to direct the stream of emigration to them and has offered particular inducements to intending colonists. Before the establishment of self-government in the Australian colonies Great Britain organized in 1837 a board of colonization commissioners, succeeded in 1840 by the Colonial Land and Emigration Board, whose chief function was to provide emigrants for the colonies by spreading information and by assisting emigrants with passage money. France in like manner provides special encouragement for French settlers in Algeria, and Germany is entering the same path as respects its possessions in Africa. Colonization societies with the support of the government authorities offer another opportunity for the state to show its interest in promoting emigration.

States which have no colonies of their own have either sought to discourage emigration or have remained indifferent to it. In the early days of the last century emigration was an offense against the law in many countries of continental Europe. Such restrictions have long since passed away and were succeeded by complete indifference, emigration becoming a private matter which the state had to tolerate, but in which it took no part. The movement has, however, reached such proportions that most of the European states have passed laws designed to protect intending emigrants and to prevent reckless emigration. Such laws exist in England, in Belgium since 1876, Switzerland since 1888, Italy since 1889, Germany and Austria since 1897. These laws have many features in common. The maritime nations prescribe rules for the transportation of emigrants and establish inspecting officers to carry them out. These rules extend to the fitness of the vessels employed, their seaworthiness, their facilities for caring for emigrants, feeding them, and providing suitable

medical attendance. They also prescribe rules for the sanitary inspection of vessels, the exclusion of persons suffering from contagious diseases, and kindred matters.

A second feature of these laws relates to immigration agents and the contract. In all the agent requires of some government authority for the prosecution of his business and is required to give bonds for his faithful observance of the law. He renders himself liable to fine or imprisonment by any false pretenses. In general these laws prescribe that the contract between the agent and the intending emigrant must be in writing. As an illustration of the scope of such laws, it may be noted that in Germany any contract which contemplates the payment of the passage money after arrival is illegal, and that no contract can be entered into in which a foreign state or society pays any part of the passage money. In Switzerland contracts must be individual, and no agreement to furnish a given number of emigrants is valid.

A third feature of such legislation is the establishment of official bureaus of information for intending emigrants. This is a special feature of the Swiss legislation, such officers to give no advice either for or against emigration, but to furnish the fullest possible authentic information upon any questions concerning foreign countries and transportation thereto which may be put to them. Such offices are intended as a corrective of the naturally glowing accounts furnished by interested agents, who, however strictly prohibited by the law from giving false information, cannot readily resist the temptation to increase their business operations.

Works which treat the subject from the standpoint of immigration are cited under that head. See COLONY; IMMIGRATION; MIGRATION.

ÉMIGRÉS, à'mé'grâ' (Fr., p.p. of *émigrer*, from Lat. *emigrare*, to emigrate). The name given to the Royalists who fled from France during the Revolution of 1789. After the disturbances at Paris and the taking of the Bastille (July 14, 1789), the princes of the royal family departed from France with a numerous following of the French nobility. In the autumn of the same year an even larger number took flight, and the climax was reached in 1791, at the time of the adoption of the new constitution. Nobles, prelates, priests, and monks crossed the frontier into Germany, Holland, and Switzerland, and even penetrated in large numbers as far as Italy. The flight of so many of the nobility brought suspicion on the King and those few who remained, and did more than anything else to make the position of the King as a constitutional monarch untenable. The

émigrés, in fact, did incalculable harm to France, not only by leaving their country at a time of grave crisis and danger, but also by plotting with her enemies at a critical moment and thus exasperating the Republicans. A court formed itself round the Bourbon princes at Coblenz; a government, with ministers and a tribunal of justice, was established, and communication was kept up with all the foreign courts unfavorable to the Revolution. Under the command of the Prince of Condé a corps of *émigrés* was formed, which attached itself to the force of the Duke of Brunswick, gathered at Coblenz. The result was that the severest laws were now put in force against the *émigrés*. Their lands were confiscated, and the penalty of death was proclaimed against any one who should support or enter into communication with them; 30,000 of the nobility were placed on the list of *émigrés* and exiled forever from the soil of France. Not until after the failure of their attempt to land at Quiberon in 1795 did they abandon all thoughts of penetrating into France by force of arms. Condé's corps, after the Peace of Lunéville (1801), was obliged formally to disband, and its leader sought an asylum in Russia. Between October, 1792, and the dissolution of the Convention more than 300 laws had been passed against the *émigrés* and their relatives. Their relatives were formed into an ostracized class, deprived of civil rights, obliged to live under police supervision, liable to a number of special fines and taxes. At the beginning of the Revolution the *émigrés* had all been nobles and traitors to France, but by 1795 this was not the case. In 1797 the Directory stated the number of *émigrés* on the lists to be 120,000, half of whom were known to be in France, and, in 1796, 300,000 of their relatives were on the proscribed lists. The reasons for this harsh treatment lay especially in the fact that the confiscated property of the *émigrés* was the security for the assignats and thus the financial basis of the Republic. Vast interests depended upon the exclusion laws. Already under the Directory (q.v.), however, many *émigrés* had endeavored to obtain permission to return to France. The general amnesty proclaimed by Napoleon as First Consul (1799) was therefore joyfully hailed by the greater portion of the *émigrés*. Many, however, did not return until after the downfall of Napoleon. Dignities, pensions, and offices were then showered upon these faithful adherents of the Bourbons; but, according to the Charter of 1814, they were unable to recover either their estates or their privileges. Finally, under the Villèle ministry, those who had lost their land estates received a compensation of 30,000,000 francs yearly, based on a capital of 1,000,000,000 francs. This was by the Law of April 27, 1825. After the July revolution, however, the grant was withdrawn. Consult: Saint-Gervais, *Histoire des émigrés français depuis 1789 jusqu'à 1828* (3 vols., Paris, 1828); Morse-Stephens, *History of the French Revolution* (London, 1891); Daudet, *Histoire de l'émigration Coblenz, 1789-1793* (Paris, 1889), and *Les émigrés et la seconde coalition, 1797-1800* (ib., 1886); Comte T. G. de Lally-Tollendal, *Défense des émigrés français* (ib., 1797); A. Sorel, *L'Europe et la révolution française* (ib., 1903); Forneron, *Histoire générale des émigrés* (3 vols., ib., 1884-90). ÉMILE OU DE L'ÉDUCATION, à'mèl' ou

de là'du'ká'syôn'. A socialistic and didactic treatise, in the form of a romance, by Jean Jacques Rousseau (1762).

EMILIA, â-mē'lyā. A division of north Italy, comprising the provinces of Bologna, Ferrara, Forlì, Modena, Parma, Piacenza, Ravenna, and Reggio nell' Emilia (Map: Italy, C 3). Area, 7993 square miles. Pop., 1901, 2,477,697; 1911, 2,740,316. Prior to its inclusion in the Kingdom of Italy, in 1860, it consisted of the former duchies of Parma and Modena and the papal Romagna. The name is derived from the Via Emilia, a highway which traverses the district and was built by the censor Æmilius Lepidus (186 B.C.) to connect with the Via Flaminia, or great northern road from Rome.

EMILIA. The wife of Iago and maid of Desdemona in Shakespeare's *Othello*, who unmasks her husband and is killed by him.

EMILIA GALOTTI, â-mē'lyā gà-lôt'tè. A tragedy by Lessing, produced in 1772. The plot is taken from the Roman story of Virginia, whose name Lessing first intended to give to the play.

EMILIA VIA. See **EMILIA**; **ÆMILIAN WAY**.

EM'ILY. The pretty niece of the retired sailor Peggotty, in Dickens's *David Copperfield*, better known by her uncle's affectionate diminutive for her name, Little Em'ly.

EMINENCE (Fr. *éminence*, Lat. *eminentia*, from *eminere*, to jut forth, from *e*, out + *minere*, to jut). A title applied in the later period of the Roman Empire to the emperors and afterward to the higher officials of the Empire. Gregory the Great authorized its application to the higher dignitaries of the church. It was restricted in 1630 by Urban VIII to cardinals, the three ecclesiastical electors of the German Empire (the archbishops of Treves, Mainz, and Cologne), and the Grand Master of the Knights of St. John. With the disappearance of the latter two classes, the title has come to be applied to cardinals only.

ÉMINENCE GRISE, á'mē'nāns' gréz, L' (Fr., the gray cardinal). The nickname given to the Capuchin François Leclerc du Tremblay (Father Joseph), the confessor of Cardinal Richelieu. (See **EMINENCE ROUGE**.) A painting by Gérôme represents him descending the palace stairway of his master, greeted by an obsequious throng in front and followed by hostile gestures, to both of which he pretends to give no heed. It was acquired by the Boston Museum of Fine Arts in 1903 for \$16,000.

ÉMINENCE ROUGE, rôozh, L' (Fr., the red cardinal). A popular nickname of Cardinal Richelieu, from his scarlet robes.

EMINENT DOMAIN. In modern public law, the right of the sovereign to appropriate the property of the subject for public purposes. This right is an incident of sovereignty and not of the paramount title which, under the feudal system of land tenure in England and elsewhere, the state enjoys. It has no affinity, therefore, with the state's right of escheat on failure of heirs, and of forfeiture for treason or felony, which, whether tenure does or does not exist in a given jurisdiction, are survivals of the feudal relation of lord and tenant. Eminent domain is more nearly allied to the state's right to take the property of its subjects or citizens by taxation, and in the exercise of the wide range of public functions comprehended

under the police power. It differs from the power of taxation in the fact that the latter always involves the notion of the equal distribution of a public burden among a number of persons, and from the exercise of the police power in that eminent domain contemplates the taking of property for use, and not its destruction, in the public interest. Neither can the exercise of this power, however arbitrarily made, be described as confiscation, as it is (1) always exercised under forms of law, (2) for the public good, and (3) in practice, at least, by making compensation for the property taken. Though usually applied to real property, the right of eminent domain extends equally to personal property. Though the term is of foreign origin and found its way into our law through its employment by Grotius, Vattel, and certain English jurists, and though it is everywhere recognized as an attribute of sovereignty, it is nowhere else in such common use as in the United States. This is doubtless due to the restraints upon the exercise of the right provided by our constitutional system, which have resulted in an elaborate judicial commentary upon its nature and the methods and conditions on which it may be exercised. Since it relates to the exercise of the sovereign power, it is in legal theory completely unfettered in those nations in which the sovereign power is wholly committed to the government. In such states, if compensation be made for property taken under the exercise of this right, it is as an act of grace and not of legal obligation. Thus, while in fact the British Parliament always provides for making due and reasonable compensation to the owner of property so taken, it is not bound to do so, nor does the validity of the exercise of the power in a given case depend at all on such provision.

Blackstone, it is true, argues that the right of the subject to compensation is a common-law right, and that the legislature can do no more than compel the owner to alienate his land for a reasonable price; but Blackstone wrote without adequate knowledge of the powers of Parliament. The statement is strictly true of the exercise of the power of eminent domain in most of the United States; but this is due to the existence of constitutional provisions by which the power of Congress and of the State legislatures is restricted, and not to any general rule of the common law.

The right of eminent domain resides in the several States of the United States as an incident of their sovereignty, and it is one of the implied powers vested in Congress by the Constitution. The restriction of the Federal Constitution upon its exercise by Congress is in the clause which declares that no person shall be "deprived of life, liberty, or property without due process of law"; and that private property shall not "be taken for public use without just compensation" (Amendments, Art. V). The Fourteenth Amendment provides that no State shall "deprive any person of life, liberty, or property without due process of law." Whether this restricts the States in exercising the power of eminent domain has not been decided, but all the States except North Carolina have bound their legislatures by similar constitutional provisions, many of the States requiring that compensation shall be made in advance. It may therefore be regarded as a part of the constitutional law of the United States that no person

can lose his property by eminent domain except it be taken (1) for public use, (2) by due process of law, and (3) for just compensation. The courts will declare unconstitutional and void any act of Congress or of a State legislature which transcends these restrictions.

The phrase "public use" has been liberally interpreted by the courts. It is held to include not only public improvements carried on directly by the State, as the construction of harbors, canals, fortifications, the erection of lighthouses and other public buildings, etc., but also private or quasi-public enterprises in which the public have an interest, as railroads, ferries, turnpikes, bridges, mills, etc. In the latter class of cases the State may act through a corporation or individual, acting as its agent, and it is no objection to the exercise of the power that it involves gain or is sought for purposes of gain by such agent.

As to what constitutes "due process of law" in such cases there is some difference of opinion. The usual procedure is by condemnation proceedings, the course of which is determined by general law. These are instituted, like any equity suit, by petition presented to a court of competent jurisdiction, and hearings may be had, either by the court or before a master or referee appointed for the purpose. The final step in such a proceeding is an order of condemnation and award, which is binding like any other judicial decree or judgment. But the legislature may substitute any other process, no matter how summary, provided only that notice of the proceedings is given to the owner of the property to be taken.

Just compensation means payment of the full value of the property taken or of any interest therein, whether present or future, vested or contingent. There has been some conflict of authority as to whether the flooding of lands or the construction and operation of an elevated railroad to the detriment of adjoining owners constitutes a "taking" of property within the sense of the constitutional provision, but the later and the prevailing view is that the owner is entitled to compensation in such cases. But for merely consequential damages resulting from public works, he must usually look for relief to other provisions of law or to the legislature.

See SOVEREIGNTY; TAX; POLICE POWER.

EMINESCU, ă-mē-ně'skōō, MICHAEL (1850-89). A Rumanian poet and publicist. He was born near Botoshani, Moldavia, and was educated at the universities of Vienna and Berlin, where he became imbued with Schopenhauer's philosophy. After his return to Rumania he successively became librarian at the University of Jassy and editor of the conservative paper *Timpul*, in Bucharest. He published his most accomplished poems in the periodical *Convorbiri literare* (Literary Conversations), the organ of the society *Junimea* (Youth). During the later part of his life he was insane. In his poems, which treat of a great variety of subjects—political, social, and religious—and which afford an insight into the deep emotional

experiences of the author, Eminescu reveals himself as the greatest lyricist of Rumania. Among his finest productions are his sonnets and his political satires. His poetical productions are characterized by plasticity of expression, reverence of the national past, and a spirit of lofty pessimism. The first edition of his collected works was published at Bucharest, under the title *Poesii* in 1884 (6th ed., 1892). Several of his poems have been translated into German by Carmen Sylva and others. Consult Bogdan, "Metrik Eminescus," in *Jahresberichte des Instit. für Rumän. Sprache*, vol. xi (Leipzig, 1904), and Scurtu, *E. Leben und Prosaschriften*, vol. x (id., 1904).

EMIN PASHA, ă-mēn pâ-shă' (1840-92). An African explorer and governor in the Egyptian Sudan. He was born at Oppeln, Prussia, of Jewish parents, his real name being Eduard Schnitzer. He studied at Breslau, Berlin, and Königsberg, taking his degree in medicine. He went to Turkey in 1864, where in the following year he received an appointment as quarantine and medical officer in the Turkish army, and in 1875 he removed to Egypt, where he became government medical officer of the Egyptian army in the Sudan under the command of General Gordon. In 1878 he was appointed by General Gordon Governor of the equatorial provinces in the southern Sudan, with the title of Bey. Emin proved himself an able administrator, and in two years the provinces, which had hitherto been a source of expense to the Egyptian government, became self-supporting. He personally conducted exploring expeditions, adding greatly to the geographical knowledge of Central Africa and securing valuable collections of botanical and zoölogical specimens.

After the revolt of the dervishes under the Mahdi in 1881 he was completely cut off from Egypt and the rest of the world, but was able to maintain himself and keep the provinces under his control. While he was still isolated from the civilized world, he was made a pasha by the Egyptian government (1887). In the following year he was rescued by an expedition led by Henry M. Stanley, who tried in vain to induce Emin to return with him to Egypt; but the Pasha would not leave his people, to whom he was devoted. In the following year, however, influenced by representations of the dervishes, the provinces rose in revolt, and Emin was deposed and imprisoned. On being released he reluctantly left the country and, returning to Egypt, resigned his office. A year later (1890) he entered the service of the German East Africa Company and accompanied Dr. Stuhlmann on an expedition to Central Africa. It was while engaged in this work, which he prosecuted with heroic energy in spite of almost extinct eyesight, that he was assassinated by two Arabs. Consult: Buchta, *Der Sudan unter ägyptischer Herrschaft* (Leipzig, 1888); Stanley, *In Darkest Africa* (New York, 1890); Schynse, *Mit Stanley und Emin Pascha durch Deutsch-Ost-Africa* (Cologne, 1890); Schweitzer, *Emin Pascha* (Berlin, 1898); P. Reichard, *Emin Pascha* (Leipzig, 1891); Vita Hassan, *Die Wahrheit über Emin Pascha* (Berlin, 1895); G. Casati, *Ten Years in Equatoria and the Return with Emin Pascha* (London, 1898); F. Stuhlmann, *Mit Emin Pascha ins Herz von Africa* (Berlin, 1894); C. Peters, *Die deutsche Emin Pascha Expedition* (München, 1891); Emin Pasha, *Eine Sammlung von Reisebriefen u.s.w.*, ed. by G.

Scheinfurth and F. Ratzel (Leipzig, 1888); *Emin Pasha in East Africa* (London, 1898).

EMIR, or **AMEER**, *ē'mēr* or *ā-mēr* (Ar. 'amīr, prince, from 'amara, to be prince, Ar. pl. *Umarā*, leader, commander, in Greek transcribed 'Αμῆρ, 'Αμῖρ, or 'Αμῖρās, Lat. *amiratus*, *amiralius*, whence the word admiral, etc.; in Persian pronunciation often abbreviated to *Mir*). A title given in Central and western Asia and northern Africa to independent chieftains, and actual or supposed descendants of Mohammed through his daughter Fatima. The latter are nominally members of the first four social orders, but have few special privileges except the right to wear turbans of green, the Prophet's color. The number claiming this descent is considerable, but they are often beggars. The leaders in the earlier religious wars of the Mohammedans had the title of emir, and it was borne as a title of nobility by several families of high rank—as, e.g., the first heads of the Omniads of Spain. As a title the word is used with others to denote distinct offices, such as 'Amir al-Mu'minin, 'prince of the faithful,' a title of the caliphs. 'Amir al-Muslimin, signifying the same thing, was a title adopted by the Almoravides. 'Amir el-'Umarā', 'prince of princes,' was the title of the first minister under the caliphs and the East Indian Moguls, who united in his own person the highest civil and military dignities. It is now the title of the governors of different provinces. The Turkish master of the horse is styled 'Amir akhur; the standard bearer, 'Amir al-'Alam; and the leader of the caravans of pilgrims to Mecca, 'Amir al-Hajj.

EMISSION THEORY OF LIGHT. See **LIGHT**; **NEWTON**, **SIR ISAAC**.

EM'MA, **ADÉLAIDE WILHELMINA THÉRÈSE** (1858—). Queen regent of the Netherlands from 1890 to 1898. She was born at Arolsen, Germany, the second daughter of Prince George Victor of Waldeck. She was married to King William III of Holland, Jan. 7, 1879, by whom she had one daughter, Queen Wilhelmina of Holland. After the death of William III (Nov. 23, 1890) she conducted the regency until the accession of her daughter to the throne, Sept. 6, 1898. She took an active interest in charities, especially hospitals for consumptives.

EMMANUEL, or **IMMANUEL** (Heb., God is with us). A name occurring in Isa. vii. 14 and viii. 8 and referred to with a special application to Jesus in Matt. i. 23. The historical connection of the name is as follows: Ahaz, King of Judah, stood in fear of a threatened siege of Jerusalem by Rezin, King of Damascus, and Pekah, King of Israel. Isaiah tells Ahaz not to fear and assures him that the threatened invasion will never come about; and as a sign for this he, unasked, says that a young woman will bear a son who will be called Immanuel, and who, while quite young, will witness the destruction of both kings. Most modern scholars see in the name no reference to Jesus and maintain that the context precludes the interpretation put upon the passage by Matthew. Just who the young woman was is a mooted question. By some she is identified with the wife of Ahaz—the child would then be Hezekiah; by others with the wife of the prophet; by still others the young woman is supposed to be indefinite and the word to mean any young woman. Consult: Porter, "A Suggestion Regarding Isaiah's Immanuel," in *Journal of Biblical Literature*, vol. xiv, pp. 19 ff. (Boston, 1895); Cheyne, *In-*

troduction to the Book of Isaiah (New York, 1895); Duhm, *Das Buch Jesaja* (2d ed., Göttingen, 1902); Marti, *Jesaja* (Tübingen, 1900); Box, *The Book of Isaiah* (New York, 1910).

EMMANUEL COLLEGE. A college of Cambridge University. It was founded in 1584 by John Mildmay, sometime Chancellor of the Exchequer under Queen Elizabeth, for a master and 13 fellows. From the first it was a "nursery of Puritanism," as Laud called it, a number of those emigrating to America in the first half of the seventeenth century being of this college. The most noted, John Harvard, gave his library and half his fortune to the American college which bears his name. There were, in 1913, 13 fellowships, 28 scholarships, besides exhibitions and prizes. There were 122 undergraduates in the same year. The college has the presentation of a number of livings and schools. Among noted men who belonged to the college are Archbishops Sancroft and Cudworth, who were masters of the college; Sir William Temple, Samuel Parr, and Bishop Hall. Consult E. S. Shuckburgh, *Emmanuel College* (London, 1904).

EMMAUS, *ēm'mā-ūs* (Gk. 'Εμμαούς, *Emmaous*). A village referred to in Luke xxiv. 13, as located "threescore furlongs from Jerusalem." The identification of its site is much disputed. 1. The early traditional location is the Emmaus (the modern 'Amwās, about 15 miles west by north of Jerusalem, near the old Roman road to Jaffa), where Judas Maccabeus won his great victory over the Syrian general Gorgias (1 Macc. iii. 40, 57; iv. 3-25) and which Bacchides later fortified (1 Macc. ix. 50). In Roman times it was the capital of one of the 10 toparchies into which Judæa for a while was divided (Pliny, *Hist. Nat.*, v. 14, 70; Josephus, *Wars*, III, iii, 5, gives a different list, which totals 11; both lists, however, include Emmaus). From the time of Julius Africanus (third century) it was given the name of Nicopolis, for what reason, however, is not definitely known (consult Schürer, *History of the Jewish People*, Eng. trans., I, ii, 253, note; II, i, 157, 159, note). The distance of this place from Jerusalem makes it impossible, in spite of its name, to consider it the village referred to by Luke. 2. From the twelfth or fourteenth century a later tradition has located the site at the modern village of *El-Kubebek*, some 60 furlongs northwest from Jerusalem, on the road to Lydda. In favor of this location is the distance, to which may be added the fact that in 1099 A.D. the Crusaders found the name *Castellum Emmaus* attached to the place, and in laying the foundations of their church cut through an older, probably Byzantine, building. (Consult Sanday, *Sacred Sites*, p. 92.) 3. Josephus tells us that after the Jewish War Titus planted a colony of 800 veterans at a village called Emmaus, 30 stadia from Jerusalem (*Wars*, viii, vi, 6). Recent opinion seems to be inclined to identify this village with the modern *Kalōniyeh*, some 35 furlongs from Jerusalem, on the road to Jaffa. In its favor is the evidence borne by the name to the colonizing of the place, just as *Lejjūn*, the modern name of Megiddo, is derived from the fact that a Roman legion was stationed there (consult Sanday, *Sacred Sites*, p. 30). As between these two latter sites, it may be impossible definitely to decide, though either of them is more probable than the first of the three. Conder's identification with the modern *Khamasah*, some 70 furlongs south-

west of Jerusalem, has a similarity of name and distance, but lacks any evidence from early literature. Consult: Schürer, *History of the Jewish People* (Eng. trans., 5 vols., New York, 1896); Sanday, *Sacred Sites of the Gospels* (Oxford, 1903); and the Bible Dictionaries.

EMMENAGOGUES (from Gk. *ἐμμηνα*, *em-mēna*, menses, from *ἐν*, *en*, in + *μήν*, *mēn*, month + *ἀγωγός*, *agōgos*, leading, from *ἄγειν*, *agein*, to lead). Medicines intended to restore, or to bring on for the first time, the menstrual flow in women. Menstruation temporarily arrested by cold, shock, etc., may be restored by warm hip baths, or sitz baths, hot mustard foot baths, and hot drinks at night. *Indirect* emmenagogues, such as iron, quinine, strychnine, manganese, cod-liver oil, etc., act by toning up the nervous system and combating anæmia. Fresh air, outdoor exercise, and sea bathing are often efficacious in the same way. *Direct* emmenagogues act as local stimulants to the uterus. They are very numerous. The most common are ergot, savin, tansy, asafoetida, rue, apiol, and myrrh. Purgatives such as aloes are useful adjuncts in the treatment of this condition. See **MENSTRUATION**.

EMMENDINGEN, *ēm'mēn-dīng-en*. A town in Baden, Germany, on the Elz, 9 miles north of Freiburg. Two modern churches, the Rathaus, and statues of the margraves Jakob III, Karl II, and Prince Bismarck are among its principal features. It has breweries and manufactures of silk, leather, photographic supplies, thread, machinery, art objects, bricks, rope, paper, tobacco, and cigars. It works stone quarries and has a trade in sea grass, wood, hemp, tobacco, and cattle. Crowning a hill 3 miles to the west are the extensive ruins of the Hochburg fortress, dismantled by command of Louis XIV in 1689, and now used as an agricultural school. Pop., 1900, 6202; 1910, 8379.

EM'MENSITE. An explosive produced by dissolving picric acid in nitric acid and mixing the crystals obtained with a nitrate, such as ammonium nitrate.

EMMENTHAL, *ēm'mēn-tāl*. An Alpine valley in the Canton of Bern, Switzerland, one of the most picturesque and fertile in the country (Map: Switzerland, B 2). It is about 25 miles long, 10 to 12 miles wide, and is traversed by the Grosse Emme and the Ilfis rivers. It raises a fine breed of cattle. The chief town in the valley is Langnau (q.v.).

EMMER. See **SPELT**.

EMMERAM, *ēm'mēr-ām*, or **EMMERAN**, **SAINT** (?—c.715). A South-German missionary, of a noble family of Aquitaine. He may have been Bishop of Poitiers. He had determined to convert the pagans of Pannonia, but was prevailed upon by the Bavarian Duke Theodo to labor in Bavaria. After rendering effective services there as a missionary during a period of three years, he undertook a pilgrimage to Rome, but was slain (according to legend on the 22d of September—now his festival; in 715 according to the best authorities; but before 696 or as early as 652 according to others) within a short distance of Regensburg by the son of the Duke, to avenge his sister's dishonor, which had been unjustly imputed to Emmeram. He was buried at Regensburg, where he had established an abbey, and where the abbey church bearing his name was built in the thirteenth century. His relics are shown there each year on the 22d of September.

EMMERAN, *ēm'mēr-ān*, **EUSEBIUS**. See **DAUMER**, **GEORG FRIEDRICH**.

EMMERICH, *ēm'mēr-ik*. A town in the Prussian Rhine Province, on the right bank of the Rhine, about 57 miles northwest of Düsseldorf and 5 miles from the Dutch frontier (Map: Prussia, B 3). The streets are broad and clean and the houses distinctly Dutch. Two of its churches are worthy of notice—that of St. Aldegund, a handsome Gothic edifice of the fifteenth century, and the Münster or church of St. Martin, with a fine crypt, a tower of the fifteenth century, carved choir stalls, and the shrine of St. Willibrord, with a golden casket of the eighth century. The town owns its gas and water works and has manufactures of liqueurs, chocolate, chemicals, leather, pianos, brushes, hosiery, oleomargarine, machinery, oil, vinegar, soap, cigars, and tobacco. Its river trade is considerable, consisting largely of produce, cattle, and Rhine salmon. Pop., 1900, 10,517; 1910, 13,418. Emmerich dates from the seventh century. In 1233 it came under the dominion of the counts of Geldern, by whom it was raised to the rank of a city, but in 1402 it passed to Cleves. In 1407 it belonged to the Hanseatic League and is believed to have contained then a population of 40,000. It subsequently shared the fortunes of the Duchy of Cleves.

EMMERICH, **ANNA KATHARINA** (1774–1824). A German nun and visionary. She was born in Westphalia and from 1803 to 1811 lived at the Augustinian monastery of Agnetenberg, near Dülmen. Like Veronica Juliani, Maria von Mörl, and others, she was believed to have been stigmatized and was particularly celebrated for her revelations and ecstatic visions of the Passion. An episcopal commission and later (1819) one from the government examined her with great care. The case seems one of the best attested of stigmatism. Her experiences were described by Clemens Brentano (Munich, 1852), whom she is said to have known from a vision and who took down her own story; and by the Abbé Cazalès (Paris, 1870). Consult Wegener, *Anna Katherine Emmerich* (New York, 1907; Eng. trans. by McGowan), and the translation of the *Passion*, with biography, by a Benedictine priest (Clyde, Mo., 1914). See **STIGMATIZATION**.

EMMERICH, **RUDOLF** (1852–). A German physician, born in Mutterstadt in the Rhine Province. In the Franco-Prussian War he served in a volunteer medical corps. He became an assistant to Von Pettenköfer and Hoffmann in the University of Leipzig, where he took his doctor's degree in 1880, and in 1887 became extraordinary, and in 1902 regular, professor of hygiene and bacteriology in the University of Munich. His more important work was on the cholera bacillus, especially in Constantinople, whither he was summoned in 1895 by the Sultan, and more generally on the bactericidal action of blood serum from artificially immunized animals; and he wrote on housing and hygiene.

EMMERPACH, **J.** See **AMERBACH**, **J.**

EMMERSON, **HENRY ROBERT** (1853–1914). A Canadian lawyer and statesman. He was born in Maugerville, New Brunswick, and was educated at Amherst Academy and Boston University. He studied law, was called to the bar, and practiced his profession at Dorchester, where he became a leader of the bar. In 1888–

90 and in 1892-1900 he was a Liberal member of the Provincial Legislature, and in 1891-92 he served in the Legislative Council. For the first five years of his second parliamentary term he was Minister of Public Works, and in 1897-1900 he was Premier and Attorney-General. In 1904-07 he was a member of the Dominion House of Commons and Minister of Railways and Canals in the administration of Sir Wilfrid Laurier. He published *The Legal Condition of Married Women*, besides pamphlets and lectures.

EMMET, LYDIA FIELD (1866-). An American portrait painter. She was born at New Rochelle, N. Y., and studied under Bouguereau and Fleury in Paris and at the Art Student's League, New York. She is especially known for her portraits of children, which show sympathetic psychological insight, unconventional composition, and resourceful though not brilliant color. She received medals at the Exposition of Chicago (1893), Atlanta (1896), and St. Louis (1905), and gained the Shaw prize in 1906, the Proctor prize in 1907, and the Clarke prize in 1909—all at the exhibitions of the National Academy of Design, of which she was elected member in 1912.

EMMET, ROBERT (1778-1803). An Irish patriot and orator. The third and youngest son of Dr. Robert Emmet, an Irish state physician, he was born in Dublin. After education at private schools he became a distinguished prize winner at Trinity College, Dublin, and an eloquent member of the Historical Society. Summoned before the faculty and governmental visitors in 1798, he resigned from college, in protest against its political domination, and traveled on the Continent, where in 1802 he had interviews with Napoleon and Talleyrand. Napoleon promised to aid Irish independence, and Emmet returned secretly to Ireland, with the idea of planning a general revolution. On July 23, 1803, an immature rising took place. Emmet, dressed in a green and white attire and attended by 100 or more conspirators, marched to seize Dublin Castle. On their way the men with pikes murdered the aged Lord Kilwarden, whom they met in his carriage, and assassinated Colonel Brown of the Fourth Regiment, who was walking on the Coombe. Emmet was in despair at these excesses, and after the ordinary guard with their first volley had dispersed the rioters, he fled to the Wicklow mountains, intending to escape to the Continent or to America. His affection for Curran's daughter led to his arrest when seeking a final interview with her. He was tried for treason, condemned to death, and hanged the following day, Sept. 20, 1803. His speeches delivered before receiving sentence and on the scaffold are held to be models of patriotic eloquence. "O Breathe not his Name," and "She is Far from the Land where her Young Hero Sleeps," two of the most pathetic poems of his college friend, Moore, commemorate the sad fates of Emmet and Miss Curran. Consult: Madden, *Life and Times of Robert Emmet* (Glasgow, 1902); T. A. Emmet, *The Emmet Family* (New York, 1898); O'Donoghue, *Life of Robert Emmet* (Dublin, 1902); *Robert Emmet: Cause of his Rebellion* (London, 1871).

EMMET, ROSINA. See **SURWOOD, ROSINA.**

EMMET, THOMAS ADDIS (1764-1827). An Irish lawyer and politician. An elder brother of Robert Emmet, he was born in Cork. He obtained a scholarship and the degree of B.A. at Trinity College, Dublin, and the degree of M.D.

at Edinburgh University. On the advice of Sir James Mackintosh, however, he abandoned medicine for law, and was admitted to the Dublin bar in 1790. As counsel of the United Irishmen, he was arrested with others for treason and imprisoned from 1798 to 1802. He regained his freedom as a political exile, forbidden to re-enter British territory under heavy penalties. He visited Hamburg, Brussels, and France, where, upon his brother's condemnation and execution, he interviewed Napoleon, who was contemplating an invasion of England. Finally he went to New York and joined the American bar. He gained distinction and a large practice, and in 1812 was elected Attorney-General of New York State. He died suddenly while pleading in court. He wrote sketches of Irish history for McNevin's *Pieces of Irish History* (1807). Consult: Haynes, *Life of Thomas A. Emmet* (London, 1829); Madden, *Memoir* (New York, 1856); T. A. Emmet, *The Emmet Family* (ib., 1898).

EMMET, THOMAS ADDIS (1828-). An American gynecologist, born at Charlottesville, Va. His father, Dr. John Patten Emmet, was professor of chemistry and materia medica at the University of Virginia. His grandfather was Thomas Addis Emmet, an Irish lawyer and a leader of the United Irishmen, afterward Attorney-General of the State of New York; and his granduncle was the Irish patriot Robert Emmet. After a partial academic course at the University of Virginia Dr. Emmet received his medical degree from the Jefferson Medical College of Philadelphia in 1850. He then acted for two years as physician in the Emigrant Hospital, Ward's Island, and after 1852 practiced medicine in New York City. From 1855 to 1862 he was also assistant surgeon, from 1862 to 1872 surgeon in chief, and from 1872 to 1900 visiting surgeon, in the Women's Hospital of the State of New York. In 1876 he was appointed consulting physician to Roosevelt Hospital, New York City. His chief literary work is his *Principles and Practice of Gynecology* (1879). He wrote also *Ireland under English Rule* (2 vols., New York, 1903).

EMMETSBURG. A city and the county seat of Palo Alto Co., Iowa, about 120 miles (direct) north-northwest of Des Moines, on the Des Moines River, and on the Chicago, Rock Island, and Pacific, and the Chicago, Milwaukee, and St. Paul railroads (Map: Iowa, C 1). It is in an agricultural, dairying, and stock-raising region and has grain elevators, flouring mills, creameries, and brick and tile and cement works. Emmetsburg contains a fine lake and a Carnegie library and owns its water works. Pop., 1900, 2361; 1910, 2325.

EMMETT, DANIEL DECATUR (1815-1904). An American actor and song writer, originator of "negro minstrel" performances. He was born at Mount Vernon, Ohio, and, after serving in the army, joined a circus company in 1835. In 1842, in association with "Frank" Brown, "Billy" Whitlock, and "Dick" Phelam, he organized the "Virginia Minstrels," which made its first appearance at the old Chatham Square Theatre, New York City, Feb. 17, 1843, and subsequently appeared in Boston and in New York City. Emmett remained until 1844. He composed the famous song of *Diwle*, afterward the war song of the South. Among his popular songs were "Old Dan Tucker," "Boatman's Dance," "The Road to Richmond," "Walk Along,

John," and "Early in the Mornin'." Consult Galbreath, *Daniel D. Emmet* (Columbus, Ohio, 1905).

EMMINGHAUS, ɛm'ming-hous, KARL BERNHARD ARWED (1831-). A German political economist, born at Niederrossla (Saxe-Weimar), and educated at Jena. He became editor of the *Bremer Handelsblatt* in 1861 and from 1866 to 1873 was professor of agricultural science in the Polytechnical School of Karlsruhe. Later he was elected director in chief of the German Life Insurance Bank at Gotha. In 1903 he retired to private life. His works on political economy include: *Allgemeine Gewerkslehre* (1868); *Das Armenwesen und die Armengesetzgebung in europäischen Staaten* (in collaboration, 1870); *a Geschichte der Lebensversicherungsbank für Deutschland zu Gotha* (1877); *Ernst Wilhelm Arnoldi, Leben und Schöpfung eines deutschen Kaufmanns* (1878).

EMMITSBURG. A town in Frederick Co., Md., 60 miles northwest of Baltimore, on the Western Maryland Railroad (Map: Maryland, E 1). In the vicinity are Mount St. Mary's College and Seminary (Roman Catholic), opened in 1803, and St. Joseph's College and Academy, conducted by the Sisters of Charity. The city contains a public library and a museum. Its industries include cattle raising and the manufacture of furniture, brooms, and hosiery. Settled about 1757, Emmitsburg received its present name in 1785, was incorporated in 1824, and under a charter of 1911 is governed by a burgess and three commissioners. Pop., 1900, 849; 1910, 1054.

EMMONS, EBENEZER (1799-1863). An American geologist, born in Middlefield, Mass. He was educated at Williams College, where he filled for a time the professorship of natural history. His research work in geology and mineralogy secured for him a position in the New York State Natural History Survey, as geologist in chief of the second district. As a result of his investigations in this field and in the New England States, he introduced a new stratigraphic division, the Taconic system (q.v.), to include a group of limestones and metamorphosed rocks that were thought to underlie the Silurian. His views in favor of the independence and unity of the system were supported for a long time by many good authorities, but it is now generally conceded that the Taconic rocks are the equivalents of Cambrian and Silurian strata. In 1838 Emmons was appointed to the chair of chemistry in the medical college at Albany, and in 1858 he was placed in charge of the geological survey of North Carolina. His most important works are: *Manual of Mineralogy and Geology* (1826); *American Geology* (1856); and the monographs published in the reports of the geological surveys of New York and North Carolina.

EMMONS, GEORGE FOSTER (1811-84). An American naval officer. He was born in Clarendon, Vt., entered the navy as a midshipman in 1828, took part in the Wilkes exploring expedition of 1838-42, and served along the California coast during the Mexican War. In the Civil War he served as commander of the *Hatteras*, capturing Cedar Keys, Fla., and Pass Christian, Miss., in 1862; was fleet captain under Dahlgren, off Charleston, in 1863; and in 1864-65 commanded a division in the Gulf of Mexico. As commander of the *Ossipee*, in 1867-68, he carried to Alaska the commissioners who took

formal possession for the United States. He became commodore in 1868, chief of the Hydrographic Office in 1870, and rear admiral in 1872, and in 1873 retired from the service. He wrote *The Navy of the United States from 1775 to 1853* (1853).

EMMONS, NATHANAEL (1745-1840). An American Congregational theologian. He was born at East Haddam, Conn., April 20, 1745, and graduated at Yale College in 1767. In 1773 he was ordained pastor of the Congregational Church in Franklin, Mass., and continued in the office 54 years. He was one of the originators of the Massachusetts Missionary Society and one of the editors of its missionary magazine, from which the *Missionary Herald* grew. He was a man of decided opinions and some eccentricity, an opponent of Freemasonry, a sympathizer with the antislavery movement, a strong Federalist, and an influential preacher. He died in Franklin, Mass., Sept. 23, 1840. Consult his *Collected Works*, with memoir by his son-in-law, Jacob Ide (New York, 1842); also Park, *Memoir of Nathanael Emmons* (Andover, 1861).

EMMONS, SAMUEL FRANKLIN (1841-1911). An American geologist, born in Boston, Mass. He graduated in 1861 at Harvard, studied in 1862-64 at the Ecole Impériale des Mines, Paris, in 1864-65 at the Freiberg (Saxony) Mining School, and in 1867 was appointed assistant geologist for the United States exploration of the fortieth parallel. In 1879 he was appointed geologist of the United States Geological Survey, in charge of the Colorado Division. He made a survey in 1870 of Mount Rainier, the loftiest point in the State of Washington. In 1903 he was president of the Geological Society of America. His publications include: "Descriptive Geology" (vol. ii of *Reports of the Exploration of the Fortieth Parallel*, 1877); *Statistics and Technology of the Precious Metals* (1885); *Geology and Mining Industries of Leadville, Col.* (1886); *Geology of Lower California* (1890); *Geology of the Denver Basin in Colorado* (1896); *Ten-mile District Special Folio, Colorado* (1898); *The Downtown District of Leadville, Colorado* (1907); *Ore-Deposits* (1913).

EMOLLIENT (from Lat. *emollire*, to soften, from *e*, out + *mollire*, to soften, from *mollis*, soft). Any substance used to soften the textures to which it is applied, as an ointment, poultice, fomentation, etc., externally, and demulcents (q.v.) internally. Examples of emollients are, in addition to the above, glycerin, lard, linseed oil, petrolatum, soap liniment, and cacao butter.

EMORY, JOHN (1789-1835). An American Methodist Episcopal bishop. He was born in Queen Anne Co., Md., studied at Washington College (Chestertown, Md.), was admitted to the bar in 1808, in 1810 was received on trial as a minister of the Methodist Episcopal church, and from 1813 to 1824 held various important appointments. In 1824 he became book agent and editor for the Methodist Episcopal church in New York City. He canceled the debt of the Methodist Book Concern and placed it upon a sound financial basis. He was elected a bishop in 1832 and assisted in the organization of Dickinson College (Carlisle, Pa.). He also originated in 1830 the new series of the *Methodist Magazine*, known as the *Methodist Magazine and Quarterly Review*, to the first two volumes

of which he contributed most of the original articles. His public writings include: *The Defence of Our Fathers* (1824) and *The Episcopal Controversy Reviewed* (1838), a reply to Bishop Onderdonk's *Episcopacy tested by Scripture*. Consult the biography by his son, Robert Emory (New York, 1841).

EMORY, ROBERT (1814-48). An American clergyman of the Methodist Episcopal church, son of John Emory. He was born in Philadelphia, Pa., graduated at Columbia in 1831, studied law, and in 1834 became professor of ancient languages at Dickinson College (Carlisle, Pa.), of which he became president in 1845. He published *A Life of the Rev. John Emory*, his father (1841), and a *History of the Discipline of the Methodist Episcopal Church* (1843), and edited an *Analysis of Butler's Analogy*, completed by G. R. Crooks (1850).

EMORY, WILLIAM HEMSLEY (1811-87). An American soldier, born in Queen Anne Co., Md., cousin of John Emory. He graduated at West Point in 1831, served on the staff of General Kearny in California during the Mexican War, and was afterward a member of the commission appointed to determine the boundary line between Mexico and the United States. In the Civil War he was promoted brigadier general United States Volunteers in March, 1862, served under McClellan in the Peninsular campaign, commanded the Nineteenth Corps under General Banks, in the Red River expedition of 1864, and afterward against Early in the Shenandoah valley. In September, 1865, he attained the full rank of major general of volunteers. He afterward commanded successively the departments of West Virginia, of Washington, and of the Gulf, and in 1876 retired with the full rank of brigadier general. He wrote: *Notes of a Military Reconnaissance from Fort Leavenworth in Missouri to San Diego in California* (1848), a "narrative" in J. C. Frémont's *Notes on Travel in California* (1849), and a large part of the *Report of the United States and Mexican Boundary Commission* (2 vols., 1857-59).

EMORY, WILLIAM HEMSLEY (1846-). An American naval officer. He was born in Washington, D. C., and graduated from the United States Naval Academy in 1866. Promoted through the successive grades, he became captain in 1901 and rear admiral in 1906. His commands include the *Bear* (1884), the *Despatch* (1885-86), the *Thetis* (1887-89), the *Petrel* (1894-96), the *Yosemite* (1898-1900), the *Monongahela* (1901), the *Indiana* (1901-03), and the *Hancock* (1904-06). He also served at the Naval Observatory and the Naval Academy, and was naval attaché in London. In 1907 he commanded the Second Squadron of the Atlantic Fleet, and in the following year he was retired.

EMOTION (from Lat. *emovere*, to agitate, from *e*, out + *movere*, to move, Skt. *mv*, to push). A highly complex mental process, or mental formation, belonging to the affective side of our nature. (See **AFFECTION**.) It includes all such experiences as joy and sorrow, hope and fear, anger and disgust. Its place in systematic psychology will be most easily understood by a comparison of the results of introspective analysis in the two great mental departments of intellect and feeling. We begin, in our treatment of these aspects of mind, with the simple elements of sensation and affection. Above the elements, in order of increasing complexity, stand

the perception or idea and the sense feeling—e.g., the perception of locality when we are touched upon the skin, and the feeling of drowsiness that comes with bodily fatigue. Above these, again, stand the association of ideas and the emotion; while at the final level of complexity we have the judgment, or the processes of the constructive imagination, and the various forms (aesthetic, moral, etc.) of sentiment. Since the highest functions both of intellect and of feeling are the prerogative of the most highly developed minds, and rarely occur in the experience of the average man, it is clear that for most of us and upon most occasions emotion is typical of the affective consciousness at large.

Let us now trace the genesis of an emotion, in order that we may have a concrete basis for future analysis. Suppose that a man is engaged in his ordinary vocation, pursuing indifferently the work that lies before him, when a letter arrives which contains a piece of bad news. The current train of ideas is sharply interrupted; there is a break in thought; the current of consciousness is changed, or (as we may say, in accordance with the definition of consciousness (q.v.) as "mind now") a novel consciousness is set up. The focal point of the new consciousness is occupied by the perception of the unwelcome tidings. If the news be overwhelmingly bad, this perception may stand almost alone; there is inhibition of other ideas, a sort of paralysis of the mind, a state of what the French term "monoideism." If it be disagreeable, but not overwhelming, all sorts of related ideas will cluster round the central perception—ideas of the consequences of the reported occurrence for one's life in the future, of its effect upon one's self and others in whom one is interested, of ways and means of mitigating the disaster—so that the perception expands to a simultaneous association of ideas or (in technical language) to an assimilation. In either case we must note that the item of news has taken possession of consciousness, as it were, in its own right; there has been no resistance to the intruding ideas. The unpleasant event has appealed as strongly and irresistibly to the attention as would a loud sound or the perception of movement in the visual field (see **ATTENTION**); in other words, the news consciousness is in a state of passive attention. Furthermore (as we have all along implied), the news is keenly and deeply felt; the assimilation, which reflects in idea the total situation that our imagined individual has to face, is washed over, colored, perhaps almost swamped, by affective processes. Finally—and this is suggested by the phrase "face the situation"—the emotion finds expression (q.v.) in certain bodily movements or attitudes; the disagreeable news may be "met" by a shrinking and cowering attitude, by a sour or bitter facial expression, perhaps by the effusion of tears or sweat; or, again, by a brace and set of the muscles and a frown of resolution. In both instances the bodily response evokes certain intensive organic sensations. These attach to the ideational elements of the central assimilation and materially enrich its contents; while their high affective value gives them a prominent part in the total "feel" of the emotion. In sum, then, an emotion arises when (1) the current train of thought is interrupted by (2) an assimilation, which represents some situation or incident in

our social or professional world. The assimilation (3) holds the passive attention and is (4) keenly felt. Moreover, the representative contents and the affective coloring of consciousness are both enhanced by (5) a complex of organic sensations, the result of the way in which the situation as a whole takes the situation in itself involved. It follows from this extreme complication of component processes that the emotion occupies a fairly long period of time, has a distinct temporal course. We should say, indeed, speaking from unanalyzed experience, that joy and sorrow, hope and fear, may dominate consciousness, not only for hours, but for days, and sometimes, with intermissions, for weeks and months; while the consequent mood or disposition may continue for years. Such a statement would miss the finer ideational trend, and the frequent of foreign consciousnesses that introspection reveals. Nevertheless, the persistence of the emotion in time, its ripening, maturing, and gradual decay, are so characteristic that Wundt gives it a temporal definition. An emotion, he says, is "a series of feelings, succeeding one another in time, which unite to form an interconnected process that is distinguished, as an individual whole, from preceding and following processes." It follows, further, from the facts of emotive "expression" that there is an intimate relation between emotion and will. Emotion differs from volition only in the point that it fades out or subsides when its course is over, to make way for customary trains of thought and habits of action; while the volition, beginning as does the emotion, ends in "a sudden change of sensational and affective contents, which brings the emotion to an instantaneous close"—i.e., in a voluntary action. See ACTION; WILL.

There is, however, another view of the nature of emotion—the James-Lange theory, as it is called—which must be noticed here. Simply stated, the theory is that emotion consists essentially of organic sensations. "The bodily changes follow directly the perception of the exciting fact," wrote James in 1890, "and our feeling of the same changes as they occur is the emotion. . . . The more rational statement is that we feel sorry because we cry, angry because we strike, afraid because we tremble, and not that we cry, strike, or tremble because we are sorry, angry, or fearful." The hypothesis rests upon three principal arguments. (1) There can be no doubt that "objects" do "excite bodily changes by a preorganized mechanism," and that "these changes are so indefinitely numerous and so varied that the entire organism may be called a sounding board" for changes in consciousness. (2) "Every one of the bodily changes . . . is felt acutely or obscurely, the moment it occurs." (3) "If we fancy some strong emotion, and then try to abstract from our consciousness of it all the feeling of its bodily symptoms, we find we have nothing left behind." In a later article (1894) James explains that by "exciting object" he means the total situation; the object as accompanied by its associated train of ideas and tinged with agreeableness or disagreeableness. The theory then asserts merely that the "rank feeling of excitement," characteristic of emotion, is mediated by the organic sensations aroused by our instinctive reaction upon the situation. Even in this form, however, it can hardly be accepted.

As regards the three points suggested above, those who are opposed to the James-Lange point out that the statement in (1) is certainly exaggerated, while that in (2) is untrue; by no means every bodily change is felt. As to (3), the organic sensations may be invariable concomitants, ingredients, or effects of emotion; they need not, however, be on that account its essential constituents. Appeal is made by the defenders of the theory to two classes of facts. (a) In pathological cases, where there is far-reaching organic anaesthesia, there is also entire or approximate absence of emotion. The opponents reply that such anaesthesia is found only where there is also found a very great weakness of the life of idea and judgment. We should therefore expect, on any theory, to find a corresponding weakening of emotion; the appeal is altogether irrelevant. (b) Emotions may be set up by purely ideational means (by the action of drugs) in which ideas and judgments play no part at all. Palpitation of the heart and feelings of suffocation produce fear; a certain amount of alcohol produces exhilaration and cheerfulness. But, it may be replied, the palpitation and suffocation are not in themselves terrifying; they terrify because they suggest the idea of death, and the quickening of the blood circulation and thrills of pleasant warmth that follow the taking of alcohol are not in themselves exhilaration; they bring with them a change in the current of ideation and an altered estimate of new-coming impressions; and it is here, in the changed situation, that we must look for the condition of the cheerful emotion. It is clear, then, that "the road to emotion lies always through the line of ideas" (Stumpf). Moreover, it is pointed out that positive arguments against the theory are at hand. (a) If the "rank feeling of excitement" is constituted of organic sensations, how is it that we are familiar with sensations as such; that we can describe them, isolate them by analysis, gauge their intensity, localize them? The sensation of nausea or of strain may be discussed as sensation, pure and simple. Under what circumstances does it lose its sense identity and become a "feeling of excitement"? The theory speaks of an "instinctive" reaction, and of bodily changes following "directly" upon the exciting fact. But it brings no evidence to show that this reflex or instinctive mode of arousal can change a sensation into a feeling of excitement. (b) If the organic sensations are of the essence of emotion, then the emotive consciousness should evince definite changes in intensity, quality, and temporal course, according as the organic sensations change in these respects. It does not, for we may have an intensive emotion without marked peripheral reactions; while, e.g., rage and extreme joy closely resemble each other in their bodily "expression," but are by no means alike in experience.

But those who cannot accept the James-Lange theory as an adequate account of the emotive process, nevertheless grant that its formulation has been, and may yet be, useful in various ways. It lays emphasis upon certain components of emotion that are too often overlooked, and so increases the accuracy of our descriptions; it warns us against an undue intellectualism, an overestimation of idea as compared with bare sentience; and it suggests a means of settling,

or at least . . . the old and vexed question of . . . of the emotions. If we could make a list of the typical situations which the adult man is called upon to face, and could tabulate in detail the bodily sets and braces, the quivers and chokings wherewith he faces them, we should gain, not a new basis of classification, for that would imply acceptance of the theory, but, at any rate, a valuable group of facts to assist us in classification. As for the attempts that have already been made, their name is legion. Emotions have been classed "as sad or joyous, sthenic or asthenic, natural or acquired, inspired by animate or inanimate things, formal or material, sensuous or ideal, direct or reflective, egoistic or nonegoistic, retrospective, prospective, or immediate, organismally or environmentally initiated" (James). It is clear that many of these divisions rest upon a nonpsychological (i.e., upon a biological, logical, or ethical) basis and must therefore be rejected by psychology. The best mode of classification at the present time is perhaps that which distinguishes primarily between *qualitative* emotions, conditioned upon the quality or character of the emotive situation, and *temporal* emotions, conditioned upon the temporal aspects of the stimuli composing the situation. Joy and sorrow, like and dislike, are emotions of quality; hope and fear, and pleasant and unpleasant surprise, are emotions of time. Within each of these main groups we may further distinguish between objective and subjective forms of a given emotion—the former characterized by emphasis upon the objective situation, the latter by emphasis upon our subjective attitude to it. Thus, joy and sorrow are subjective, while like and dislike, sympathy and antipathy, attraction and repulsion, are objective. Finally, we may mark off various degrees of intensity of a typical emotion, as melancholy and wretchedness, or friendliness, affection, and love.

See AFFECTION; ANGER; FEAR; FEELING; MOOD; SENTIMENT.

EMPANEL, or IMPANEL. To place names of jurors on a list. Formerly a little pane or oblong piece of pavement was used for this purpose, and the list is still called a panel (q.v.). In . . . the term is applied generally to the : . . . sheriff in making the list of jurors who have been summoned for a designated term of court. While used in this sense in the United States, it is more frequently employed to denote the selection of a jury for the trial of a particular case. Thus, a jury is said to be impaneled when its membership has been determined and it has been sworn to try the case. Consult the authorities referred to under JURY.

EMPECINADO, ɛm-pə'thē-nā'dō, DON JUAN MARTÍN DÍAZ, EL (1775-1825). A Spanish patriot, a leader of guerrillas. He was born at Castrillo de Duero, in the Province of Valladolid, and at the age of 17 joined the army. At the head of 5000 or 6000 men he carried on a fierce and successful warfare against the French during the Peninsular struggle. In 1814 he was appointed colonel in the regular army, and the King himself created him field

marshal; but in consequence of his petitioning Ferdinand VII in 1815 to reinstitute the Cortes, he was imprisoned and afterward banished to Valladolid. On the outbreak of the insurrection in 1820 he took a prominent part on the side of the Constitutionalists and on several occasions exhibited great courage. He was taken prisoner in 1823 and, on the restoration of Ferdinand, El Empecinado was exposed in an iron cage, and after a miserable imprisonment of two years was sentenced to be hanged. Resisting his executioners, he was stabbed to death. The name El Empecinado, by which this guerrilla hero was popularly known, was a nickname, meaning "the man covered with pitch." It is the name given by natives of other villages to natives of Castrillo, because near Castrillo there are two streams that form a black mud called by the natives *pecina*. At the request of Juan Martín Díaz, a royal cedula declared *el Empecinado* to be the patronymic of the family.

EMPEDOCLES (Lat., from Gk. Ἐμπεδοκλῆς, *Empedoklēs*). A Greek philosopher, of the fifth century B.C. He was born of a distinguished family at Agrigentum in Sicily and was held in high esteem by his fellow citizens for his skill in medicine and rhetoric as well as for his ability as a philosopher. He used his influence to help establish a democracy in his native city. After his death marvelous tales were current of his powers as a magician which, tradition said, enabled him to turn away pestilential winds, to recall to life a girl thought to have been long dead because in a trance, and to perform similar miracles. Indeed, it would seem from his own verses, preserved by Diogenes Laërtius (q.v.), 8, 62, that he claimed to be immortal and accepted as his right all the honors shown him by his contemporaries. Of his death various traditions were current in later antiquity. The most familiar of these said that he leaped into the crater of Etna (consult Matthew Arnold's *Empedocles on Etna*); another that he was translated while his companions slept; but a third said that he died a natural death in the Peloponnesus. Empedocles was possessed of considerable poetic gifts and left behind him two poems—one on Nature (Περὶ Φύσεως), which set forth his theory of the universe; in the other, entitled *Kathappol*, of ethical import, he exhorted his fellow citizens to lives of purity. In this latter poem he seems to have adopted the Pythagorean doctrine that some souls at least, to be purified, must migrate through many bodies. Of the former poem about 400 verses, of the latter about 100, have survived.

In philosophy Empedocles was an eclectic, attempting a combination of the teachings of the Eleatic school (q.v.) as to being and of Heraclitus' doctrine of becoming. Following the teaching of the Eleatics as to being—eternal and imperishable, he assumed four elements—earth, air, fire, and water—mutually indervative, independent principles, which, however, are capable of being divided. That these four elements differ qualitatively, and therefore cannot consist of pure being, was a difficulty which did not occur to him. To account for the changing phenomena of the visible world, he employed the principle of "becoming" enunciated by Heraclitus (q.v.), but postulated as the two primal dynamic causes of change, "Friendship" (φιλότης) and "Strife" (νεῖκος), of which the first is the uniting, the second the separating, principle; these primal powers or forces he thought of as

divine. The two powers always existed coincidentally; now one, now the other was in the ascendant. In the beginning, according to Empedocles, the four elements existed together immovable in the Sphere (*σφαῖρος*), the perfect primitive world, where they were maintained by Friendship, until Strife, which originally was outside, gradually made its way into the Sphere and separated the elements and gave rise to individual and contrary phenomena. The two principles, Friendship and Strife, by action and interaction produce constant change, and ultimately the world must again return to its original unity, only to give birth to a new system, and so on indefinitely. By attributing to his four elements immutable being, so that they cannot arise out of one another or be changed one into another, Empedocles made an advance over the early Physicists, and by recognizing in contrast to the Eleatics that change actually exists, and by . . . causes, he places in a new light . . . between matter and its informing principles. On many points Empedocles' views are not clear; but his theory of knowledge is of especial interest, for he was the first to state clearly the doctrine that like is known by like, i.e., that the mind perceives only that which is by nature cognate or analogous to it, that we ourselves are composed of the same elements which make up all things of which we can have any knowledge.

Empedocles was greatly admired in antiquity, especially by Aristotle and Lucretius (q.v.). The latter chose him as his model, although he criticized his philosophy. The fragments of Empedocles' work have been published by Mullach, *Fragmenta Philosophorum Græcorum*, vol. i (Paris, 1860); Ritter and Preller, *Historia Philosophiæ Græcæ* (9th ed., Gotha, 1913); Diels, *Die Fragmenta der Vorsokratiker* (3d ed., 1912). A translation into verse was made by Leonard (1908). Consult also: Gladisch, *Empedokles und die Aegypter* (Leipzig, 1858); Lommatsch, *Die Weisheit des Empedokles, etc.* (Berlin, 1830); Ritter, *Ueber die philosophische Lehre des Empedokles* (ib., 1820); Baltzer, *Empedokles* (Leipzig, 1879); Zeller, *Philosophie der Griechen*, vol. i (ib., 1881); Ueberweg, *History of Philosophy*, vol. i (trans., New York, 1872); Erdmann, *History of Philosophy*, vol. i (trans., London, 1889); Bidez, *La biographie d'Empédocle* (Ghent, 1894); *North British Review*, vol. xlv (Edinburgh, 1888); Fairbanks, *The First Philosophers of Greece* (New York, 1898); Gomperz, *Greek Thinkers*, vol. i (ib., 1905); Bakewell, *Source Book in Ancient Philosophy* (ib., 1907); Masson, *Lucretius, Epicurean and Poet* (New York, 1907-09); Clara E. EMPEDOCLES ON ETNA. A poem by Matthew Arnold, best described as a dramatic monologue, interspersed with songs after the manner of the Greek chorus. It appeared in 1867.

EMPEROR (OF. *empeireor*, Lat. *imperator*, OLat. *induperator*, from *imperare*, to command). The original signification of this, which in the modern world has become the highest title of sovereignty, can be understood only when it is taken in conjunction with *imperium* (q.v.), which in the Roman political system had a peculiar and somewhat technical meaning. The

imperium of a magistrate was the power which he possessed of bringing physical force into operation for the fulfillment of his behests. The term was specially applied to the military authority exercised by a magistrate in command of an army away from Rome. The name "imperator" thus came to denote in particular a commander of troops; after a victory such a commander was specially hailed by his army as imperator. The *imperium* was conferred by a *lex curiata*, and it required this authorization to entitle a consul to act as the commander of an army. In the case of the kings, also, the *imperium* was not implied in their election, but was conferred separately, by a specific act of the national will. Now, it was in virtue of this *imperium* that the title "imperator" was given to its possessor. Far from being an emperor in the modern sense, he might be a consul or a proconsul; and there were, in fact, many *imperatores*, even after the title had been assumed as a *prænomen* by Julius Cæsar (58-44 B.C.). It was this assumption by Julius Cæsar which gradually gave to the title its modern signification. In republican times it had followed the name (see *NOMEN*), and indicated simply that its possessor was an imperator, or one possessed of the *imperium*; now it preceded it, and signified that he who arrogated it to himself was *the* emperor. In this form it appears on the coins of the successors of Julius. After the times of the Antonines the title grew into use as expressing the possessor of the sovereignty of the Roman world, in which sense *princeps* also was frequently employed. Consult: Schuckburgh's edition of the *Augustus of Suetonius*, pp. xix-xxviii (Cambridge, 1896); Jones, *The Roman Empire* (New York, 1908); and the articles "Imperium and Imperator" and "Princeps," in Smith, *A Dictionary of Greek and Roman Antiquities* (2 vols., 3d ed., London, 1890-91).

The title "emperor" was used by the rulers of the Byzantine realm down to its extinction in 1453. From the emperors of the West the title passed to Charlemagne, the founder of the German Empire. When the Carolingian family expired in the German branch, the Imperial crown became elective, and continued to be so till the Holy Roman Empire came to an end—Francis II, who in 1804 had declared himself hereditary Emperor of Austria, . . . it down in 1806. In addition to . . . of Austria there are in Europe the Emperor of Russia and Emperor of Germany. In 1876 the Queen of . . . umed the title of Empress of India, . . . to those which she bore previously; the King of England is now Emperor of India. See *EMPIRE*.

EMPEROR BOA. See *BOA*.

EMPEROR BUTTERFLY and MOTH.

1. A group of butterflies of the southern United States. The best-known species is the goatweed butterfly (*Pyrrhanæa andria*), dark brown and orange in colors, which occurs from Illinois to Texas, the larvæ of which feed on the goatweed (Croton). 2. A large British moth (*Saturnia pavo-minor*) of the family Saturniideæ, about 2½ inches across the expanded wings, which are gray in the female and in the male are reddish brown on the fore wings and rusty yellow on the hinder wings; each wing is ornamented with a large, eyelike, glassy, and transparent spot. It is the largest British moth, but is much exceeded in size by the congeneric peacock moth (*Saturnia pavo-major*) of the continent

of Europe and Asia. Both are closely allied to the silkworm.

EMPEROR FISH. One of the largest and most gaudy of the coral fishes (q.v.), characteristic of the genus *Holacanthus*, which differs from other chaetodonts in having the gill cover armed with a stout, backward-pointing spine. The emperor fish (*Holacanthus imperator*) is found from East Africa to Malaya, reaches a length of 15 inches, and is deep blue, marked with many golden-yellow stripes running from head to tail, while the head is richly ornamented with black and gold. Hence the name "emperor of Japan," applied by the Dutch of the East Indies, seems appropriate. Its flesh is regarded as superior to that of almost any other East Indian fish, resembling salmon. This genus contains some 40 species, widely distributed in tropical seas, some of which, as the large, beautiful, and toothsome isabelita, or angel fish (*Holacanthus ciliaris*) and the black angel fish (*Holacanthus tricolor*), illustrated on the Plate of CORAL FISHES (q.v.), frequent the coral reefs of Florida, Bermuda, and the West Indies, and occasionally stray northward.

EMPE/STRUM. See CROWBERRY.

EM/PHASIS. See ACCENT.

EMPHYSE/MA (Neo-Lat., from Gk. ἐμφύσημα, inflation, from ἐν, *en*, in + φυσᾶν, *physan*, to blow). An unnatural distention of a part with air. It is rarely that emphysema is produced otherwise than mechanically; but collections of fluid in a state of decomposition sometimes give out gases which penetrate and distend the textures with which they are in contact. A form of emphysema attended by gangrene occurs as a result of microbic infection.

Emphysema of the lung is a condition in which the partitions between the air cells or vesicles are ruptured and absorbed, thus throwing numerous small cavities into one. The result is diminished elasticity of the lung tissue and deficient expansion of the organs. It is generally due to long-continued strain, as in using wind instruments, or to chronic bronchitis, or as a phenomenon of old age.

EMPHYTEU/SIS (Lat., from Gk. ἐμφυτεύσις, an implanting, from ἐμφυτεύειν, *emphyteuein*, to implant, from ἐμφυτός, *emphytos*, implanted, from ἐμφύειν, *emphyein*, to implant, from ἐν, *en*, in + φύειν, *phyein*, to plant). At Roman law, a perpetual, alienable, and heritable right of possession of land enjoying agricultural property in return for the payment of an annual ground rent. This institution, as it is found in the laws of Justinian, had two roots. 1. In Italy, during the period of the Roman Republic, assignments of lands belonging to the Roman people or to a municipality were made to private persons, nominally at the pleasure of the Roman people or of the municipality, but practically on an indefinite, alienable, and heritable tenure; and for the use of these lands a fixed payment (*vectigal*) was made. Lands so held were termed *agri vectigales*. 2. In the eastern provinces of the Roman Empire tracts of unimproved land were granted, on a perpetual tenure, for improvement or "plantation" (*emphyteusis*), in consideration of a fixed annual ground rent (*canon*), which was regularly based on the value of the unimproved property; and such grants were not infrequently made by private proprietors. When the Empire became Christian, such grants were made also by churches and monasteries.

Neither of these institutions, *ius in agro vectigali* or *emphyteusis*, could be brought under the Roman law of lease (*locatio conductio*), because the Roman lessee had no protection against third persons except through his lessor, and no protection against his lessor except, in case of breach of contract, by action for damages; while the holder of an *emphyteusis* was protected against his landlord, and the holders of *ius in agro vectigali* or of *emphyteusis* enjoyed the same rights of action against third persons as if they were owners. Both therefore had, what the Roman lessee had not, a right in the land itself. These two institutions were fused by Justinian into one. As against the landlord, the emphyteutist had the right of possession and enjoyment, under the following limitations: he must keep the land in cultivation; he must pay the taxes on the land; he must pay the annual ground rent to his landlord; and, if he proposed to sell his right, he must inform the landlord of his intention and of the price offered. The landlord had then the right either to buy the *emphyteusis* himself at the same price or to exact 2 per cent of the price. The landlord had the right of reentry upon the land when it was sensibly deteriorated by neglect or misuse, when taxes or ground rent had not been paid for three years, when notice of intention to sell was not given, or when the price offered was not truthfully stated. Teutonic law developed a similar institution, known as heritable leasehold (*erbpacht*).

Mediæval jurists were inclined to construe both *emphyteusis* and *erbpacht* as a divided ownership, attributing titular ownership to the landlord and beneficial ownership to the occupant. (See DOMINIUM.) The revolutionists of the eighteenth and nineteenth centuries disliked these perpetual leaseholds as savoring of feudalism; and in many states the ground rents were either abolished or provision was made for their redemption. In some European states, however, the institution survives, sometimes under the name of *erbpacht*, sometimes under that of *emphyteusis*, with more or less blending of Roman and mediæval rules. See CENSO; SUPERFICIES; CIVIL LAW; and compare the analogous doctrines of English and American law under the titles LEASEHOLD; RENT (*Rent Service*, *Rent Charge*); FEUDAL TENURE.

EM/PIRE (OF., Fr. *empire*, from Lat. *imperium*, power, from *imperare*, to command). The territory and people whose sovereign bears the title of emperor or empress—a title which, since the time of Julius Cæsar, has come to imply the possession of monarchical power in its highest form. (See IMPERIUM.) The Roman Empire, from 395 A.D., was divided into two parts—one of which was ruled from Rome, the other from Constantinople. The Empire of the West succumbed to the onslaught of the Germanic nations in 476, while the Eastern, or Byzantine, Empire survived until 1453. Charles the Great, King of the Franks, was crowned Emperor at Rome by Pope Leo III in 800. Thus the Empire of the West was nominally revived, and the title of Emperor of the Romans continued to be borne by his successors for nearly a century. About 50 years after the extinction of the Carolingian dynasty in Germany, the German King Otto the Great, after conquering the Lombards, had himself crowned Emperor by the Pope at Rome in 962, from which year dates the Holy Roman Empire of the German

nation, frequently spoken of simply as the "Empire." From Otto's time, with the exception of the short period of the Interregnum in the thirteenth century, there was an unbroken succession of elected German kings, who assumed the rank and right of emperors and were acknowledged as such by the church. The Holy Roman Empire came to an end in 1806, after its last ruler had assumed the title of Emperor of Austria. In 1871 the German states, with the exclusion of Austria, were constituted an empire, the dignity of German Emperor being made hereditary in the royal dynasty of Prussia. In addition to the three empires of Christendom—Germany, Austria-Hungary, and Russia—the Turkish, Japanese, and Abyssinian realms are spoken of as empires, while the King of England bears the title of Emperor of India. Previous to 1889 Brazil was an empire. See EMPEROR; HOLY ROMAN EMPIRE; GERMANY.

EMPIRE, ROMAN. See EMPEROR; EMPIRE.

EMPIRE STATE. New York. See STATES, POPULAR NAMES OF.

EMPIRIC (Lat. *empiricus*, Gk. *ἐμπειρικός*, *empeirikos*, empire, from *ἐμπεiros*, *empeiros*, skilled in, from *ἐν*, *en*, in + *πείρα*, *peira*, trial). The name applied to a sect of ancient physicians in the time of Celsus and Galen. They laid great stress on the unprejudiced observation of nature, and thought that, by a careful collection of observed facts forming a history, the coincidence of many observations would lead to unalterable prescriptions for certain cases. The later adherents of the school excluded all theoretical study, even that of anatomy, and were guided solely by tradition and their individual experience. By an empiric in medicine is now understood a man who, from want of theoretical knowledge, prescribes remedies by guess according to the name of the disease or to individual symptoms, without knowledge of the pathological conditions, the chemical changes occurring, or the individuality of the patient; in other words, a quack. Many so-called "specific medicines" are administered on this principle, or want of principle.

EMPIRICISM (Gk. *ἐμπειρία*, *empeiria*, experience, from *ἐμπεiros*, *empeiros*, skilled in). The philosophical view that experience is the source of all knowledge. Until recently the term "empiricism" has been applied to the view held mainly by English writers of the seventeenth, eighteenth, and nineteenth centuries. John Locke was the first to give it systematic expression, but Francis Bacon before him was in temper an empiricist. Classical English empiricism can be succinctly stated as follows, although not every early English empiricist is to be considered as subscribing to what may be called this standardized empiricism. This empiricism denies the existence of any *a priori* (q.v.) constituents in knowledge, maintaining that at first the mind is a *tabula rasa*, or clean slate, upon which experience must inscribe all the characters. These inscriptions come one by one, and what seems to be a necessary connection appears so only from the habit we have formed of associating certain elements together. Even in antiquity there were thinkers with distinctly empiricist proclivities, as, e.g., the Sophists (q.v.). (See LOCKE; HUME; MILL, JAMES; MILL, JOHN STUART.) The fault of this classical English empiricism is not that it traces all knowledge back to experience, but that it gives a wrong account of experience, representing it

as a piecemeal affair, an aggregation of psychological elements with an accidental structure. Opposed to this empiricism stood the continental rationalism (q.v.) represented by such philosophers as Descartes, Spinoza, Leibnitz, and Wolff, who championed the ability of the mind to know reality by means of its faculty of reasoning, which was for them independent of experience. Kant attempted a compromise between empiricism and rationalism, restricting knowledge to the domain of experience (thus agreeing with the empiricists) but attributing to the mind a constructive function, in building the raw materials of sensations into the systematic structure of experience. This structure can be known *a priori*, without resorting to empirical methods. (In this respect Kant agreed with the rationalists.)

In recent years the term "empiricism" has taken on a more flexible meaning, being now used quite frequently of any philosophical system which finds all its materials in experience, even when experience is not considered as atomic in constitution, i.e., as an accidental collection of psychic elements. William James thus called his own philosophy "radical empiricism," distinguishing it from traditional empiricism by the fact that the latter "has always shown a tendency to do away with the connections of things and to insist most on the disjunctions," while his own empiricism "does full justice to conjunctive relations, without, however, treating them as rationalism always tends to treat them, as being true in some supernal way, as if the unity of things and their variety belonged to different orders of truth and validity altogether." This radical empiricism holds "that the relations between things, conjunctive as well as disjunctive, are just as much matters of direct particular experience, neither more so nor less so, than the things themselves." The world is composed of experiences, each connected by some experienced relation with some other experience. Time and space are common media in which these constituent experiences lie, but there is no one consciousness in which the whole is included.

John Dewey has also contributed to a more liberal construction of empiricism, calling his own view an "immediate empiricism," which "postulates that things—anything, everything, in the ordinary or nontechnical use of the term 'thing'—are what they are experienced as. Hence, if one wishes to describe anything truly, his task is to tell what it is experienced as being." Knowledge is itself a form of experience and must be treated descriptively as it is found: "go to experience and see what the thing is experienced as." Immediate empiricism is thus a method, the empirical method universally applied. For the traditional empiricism, consult: Green, *Prolegomena to Ethics* (5th ed., Oxford, 1884); Pfeiderer, *Empirismus und Skepsis in Dav. Hume's Philosophie* (Berlin, 1874); and the histories of philosophy by Windelband, Höfding, Ueberweg, Erdmann, Fischer, Falckenberg. For the more recent empiricisms, consult: James, *The Meaning of Truth* (New York, 1909); *Essays in Radical Empiricism* (ib., 1912); *Pluralistic Universe* (ib., 1909); *Some Problems of Philosophy* (ib., 1911); Dewey, *Influence of Darwin on Philosophy* (ib., 1910).

EMPIS, ἔμ'πῆ, ADOLPHE DOMINIQUE FLORENT JOSEPH SIMONIS (1795–1868). A French dramatist, born in Paris. From 1856 to 1859 he

was administrator of the Théâtre Français. He is the author of a number of plays which have been praised for their natural style, their dramatic situations, and their fine study of character. These productions include: *Bothwell* (1824); *La mère et la fille*, with Mazères (1830); *Un changement de ministère* (1831); *Un jeune ménage* (1838); *L'Héritière* (1844); *Les six femmes de Henri VIII* (2 vols., 1854).

EMPLOYERS' LIABILITY. In general, the liability of employers for injuries sustained by workmen while in their employ. (See NEGLIGENCE; TORT.) Specifically the expression is most frequently employed to describe certain statutes, recently enacted in England and the United States, with the object of defining and enlarging this common-law liability.

A person being generally liable, not only for his own direct acts of negligence, but indirectly for those of his servants as well, it might be supposed that an employee injured in consequence of such negligence, either on the part of his employer or of a fellow employee, would be entitled to recover damages from his employer for the injury so sustained. But the nature of the relation of master and servant at common law, and the conditions of service formerly existing, have led to a peculiar rule limiting the liability of employers to their employees as distinguished from other persons exposed to injury from the manner in which the business is carried on. This rule is to the effect that an employee, on entering upon his service, implicitly engages with his employer to run all the ordinary risks of the service, including the risk of negligence on the part of his fellow servants. The employer is, of course, liable for gross negligence, and for novel and extraordinary risks involved in the service, as well as for all acts of negligence, whether of the master or of fellow servants, occurring outside the regular service; he is bound to use due diligence in selecting his superintendents, foremen, and other servant, to furnish them with suitable appliances and a safe and proper place in which to carry on their work and to make necessary rules. It makes no difference whether the negligent fellow servant through whose fault an injury is sustained is a foreman, whose orders the injured servant was bound to obey, or a fellow servant in the ordinary sense, working side by side with the injured man. The "risk" voluntarily assumed by the man who enters another's employ covers "all persons engaged under the same employer for the purposes of the same business, however different in detail those purposes may be."

With the change in the relations of employer and employee, due to the transformation of industrial conditions in recent years, these rules of the common law have taken on a harsh and arbitrary aspect, which under older conditions they did not present. They have accordingly been modified by legislation, both in England and in the United States. The earliest statute of this sort was the Employers' Liability Act, passed by Parliament in 1880 (43 and 44 Vict., c. 42), with the avowed object of extending and regulating the liability of employers to make compensation for personal injuries suffered by workmen in their service. It exempted workmen from the common-law doctrine when injury was due to defective work or machinery, putting them in much the same position with respect to their employer as that occupied by an out-

sider, and by excluding from the definition of fellow servants foremen and others exercising authority over the injured employee, making the employer liable for the acts of those exercising a delegated authority under him. It also abolished the immunity of persons and corporations operating railroads in all cases of injury suffered by railroad employees in consequence of collisions and other railroad accidents. This statute was followed in 1897 and 1900 by the Workmen's Compensation Acts (60 and 61 Vict., c. 37, and 63 and 64 Vict., c. 22), which in certain large classes of employment, as railways, factories, mines, etc., render the employer liable for any personal injury incurred by a workman by any accident arising out of and in the course of his employment, whether due to the fault of the employer or not; and these acts were in 1907 superseded by the Workmen's Compensation Act, 1906 (6 Edw. vii, c. 58), which removes the restriction of the principle to special classes of employment and makes it of nearly universal application. Under this legislation the employer is virtually an insurer of all persons in his employ against all injuries sustained in the course of their employment, paying a limited compensation to those injured or to the families of those killed by such accidents, whether or not due to want of care on his part or that of his servants.

The American legislation on this subject is of a very diverse character, most of the States having passed statutes enlarging the liability of the employer of labor. In some States this liability has been confined to employees of railroad companies; and in some the disposition to evade the new rule of liability, by requiring an employee to sign a contract waiving the benefits of such legislation, has been defeated by further statutes forbidding the making of such contracts or declaring them to be null and void. The English Act of 1906 has been followed in several States, including New York, New Jersey, Massachusetts, Wisconsin, and others, and by an act of Congress applying to persons engaged in interstate commerce.

The constitutionality of this legislation has been questioned on the ground that, where the employer was free from fault, the provision of compensation to the employee was a taking of property not for a public purpose and without due process of law. In 1911 the New York Court of Appeals declared the Workmen's Compensation Act of that State unconstitutional and void on that ground. This decision was very unpopular and was severely criticized by a large section of the bar as well as by the public, and furnished one of the principal grounds for the proposal, embodied in the Progressive platform of 1912, for the so-called "recall of judicial decisions" by popular vote. In 1913 the New York constitution was amended so as to permit legislation of this character. Substantially similar acts have recently (1913-14) been sustained as constitutional by the Supreme Court of Wisconsin and the Supreme Court of the United States.

The extension of employers' liability by the legislation above described has led to the institution of a novel kind of insurance, known as employer's liability insurance, whereby the employer is insured against loss by reason of his liability to his employees; the insurer, in consideration of a premium paid by the employer, agreeing to pay all damages with which the lat-

ter is or for which he may become legally liable. Recent employers' liability acts make such insurance compulsory and in some States the State itself provides such insurance.

EMPLOYERS' LIABILITY INSURANCE. See INSURANCE; ACCIDENTS, INDUSTRIAL.

EMPLOYMENT BUREAU. Any agency intended to bring employers and the unemployed together. There are four kinds: (1) private trade-unions for skilled labor; (2) labor societies; and (3) free bureaus established by national or local governments. The free bureaus have in view the larger object of adjusting the entire labor market. The fullest expression of this method has been found in France, where in 1851 a comprehensive scheme for the establishment of employment bureaus throughout the country was submitted to the Legislative Assembly. The measure failed of adoption; but the idea was persistently agitated until Oct. 7, 1888, when the Bourse de Travail was opened in Paris with a subsidy of 150,000 francs from the government. A large building was erected in 1892 which became the headquarters of labor syndicates. Owing to a dispute between the labor syndicates and the administration, it was closed July 6, 1893. It was reopened in 1896, and is at present under the management of a commission chosen in part by the labor syndicates, in part by the administration. There are also throughout France numerous bureaus managed by unions of labor syndicates. These ordinarily seek to place members of syndicates—or unions—alone, though they may extend their assistance to other workmen with the hope of inducing them to join the syndicates. A national bureau has been established with the purpose of supplying labor in different parts of the country. This bureau received in 1900 an appropriation from the state; but since it was founded to employ its influence to keep workers away from districts where strikes are in progress, government aid has been withdrawn from it. Public bureaus have been opened in 49 other cities. In 1870 the system was established in Belgium with good results. In England the movement began with the Egham bureau, established in 1885, and discontinued after the passing of the Local Government Act in 1894. Another voluntary bureau was established in Ipswich in 1885 and operated until 1906, when its work was taken over by the Distress Committee. Several municipal bureaus were established in the depression of 1892. Official inquiry in 1905 disclosed the existence of 21 municipal and three nonmunicipal bureaus. Few of the bureaus showed any considerable degree of activity, and their work was taken over by Distress Committees under the local governments, which attempted—with no very brilliant success, as a rule—to meet the

need of organization of the labor market. By Act of 1909 the establishment of employment bureaus, or labor exchanges, was made compulsory throughout the United Kingdom. Under this act 423 labor exchanges had been established by 1914, with 1066 local agencies, each directed by the nearest exchange. The system is controlled by a central office in London, with eight divisional offices in various cities. The system has been successful in organizing the market for casual and unskilled labor. Switzerland has offices at Bern and Basel, and since 1889 several Italian cities have started labor exchanges, the most important being at Milan. In Germany the movement is recent, but extensive. In addition to the official bureaus there exist employers' unions and joint associations of employers and trade-unions. The first municipal bureau grew out of such an association started in Berlin in 1892. Bureaus organized by municipalities have been especially successful in southern Germany. The best system is that of Munich, with an elective board of employees and employers, having a city officer as chairman. In its first year of full operation (1896) the Munich bureau found situations for 25,586 persons, and its work has rapidly increased in effectiveness. At present there is a municipal labor bureau in almost every German city of over 50,000 inhabitants and in many of the lesser cities as well. In north Germany the voluntary association, subsidized by the municipality, performs much of the work conducted in south Germany by purely municipal agencies. There is a considerable degree of coöperation among the agencies of the several municipalities to the end of organizing a national labor market. In the United States the private agencies play an important part in adjusting the conditions of the labor market. Since it is usually laborers of the lowest and most ignorant classes who are compelled to make use of an agency for finding employment, it has been easy for unscrupulous parties to secure great profits through the establishment of fraudulent bureaus. A number of States have attempted to meet this evil by requiring the licensing of private employment bureaus or the furnishing of bonds. In other States public labor bureaus have been established with the hope of destroying private agencies altogether. Ohio, as the pioneer by the Law of April 28, 1890, started bureaus in five cities. State laws providing for public employment bureaus were in force in 18 States in 1914. Most of these bureaus are under the management of the labor departments of the respective States and, through lack of adequate machinery, accomplish practically nothing. The most successful law is that of Wisconsin, giving to the Industrial Commission, created in 1911, broad powers to organize and conduct employment bureaus. A competent staff was chosen to establish an employment bureau at Milwaukee in 1912. In its first year of operation the bureau secured positions for 11,400 applicants, and its second year of operation showed an increase of 40 per cent in work done. Three other bureaus have been opened in other cities. The philanthropic agencies are the charity organizations, Young Men's Christian Associations, churches, settlements, and the Salvation Army. In recent years, owing to the publications of investigations revealing the iniquities of the private agencies, a number of semiphilanthropic agencies have been established by employers. Consult:

EMPLOYMENT DISEASES. See OCCUPATIONAL DISEASES.

EMPOLI, ĕm'pŏ-lă. An episcopal city of the Province of Florence, Italy, on the left bank of the Arno, 19 miles west of Florence (Map: Italy, E 4). Empoli manufactures straw plaiting for bottles, cotton and leather goods, hats, faience, glass, and macaroni, and market fruits and vegetables. Pop. (commune), 1901, 20,404; 1911, 21,566.

EMPOLI, JACOPO DI CLEMENTI DA. See CLEMENTI, JACOPO DI, DA EMPOLI.

EMPORIA. A city and the county seat of Lyon Co., Kans., 61 miles southwest of Topeka, on the Missouri, Kansas, and Texas, and the Atchison, Topeka, and Santa Fe railroads (Map: Kansas, F 6). It is the seat of the College of Emporia (Presbyterian), opened in 1883, a State normal school, and the Emporia School of Music and Art, and contains a fine Federal building, a Carnegie and a railroad library, and a hospital. Emporia is in a fertile agricultural region, ships large quantities of cattle, and has flouring mills, foundries and machine shops, corrugated-metal works, carriage factories, marble works, ice and cold-storage plants, and wholesale houses. Emporia was settled in 1856, incorporated in 1870, and adopted the commission form of government in 1910. The water works are owned and operated by the city. Pop., 1900, 8223; 1910, 9058; 1914 (U. S. est.), 9328.

EMPO'RIUM. A borough and the county seat of Cameron Co., Pa., 100 miles west-northwest of Williamsport, at the junction of the Buffalo and Philadelphia and Erie divisions of the Pennsylvania Railroad (Map: Pennsylvania, E 3). It has large powder plants and manufacturing of incandescent lamps, paving brick, flour, iron, lumber, sole leather, etc. The electric-light plant is owned by the municipality. Pop., 1900, 2463; 1910, 2916.

EMP'SON, WILLIAM (1791-1852). An English editor. He was educated at Winchester and at Trinity College, Cambridge, and was one of the most active contributors to the *Edinburgh Review* from 1823 to 1849, becoming editor of that publication upon the death of Napier in 1847. From 1824 until his death he was professor of law at the East India College, Haileybury.

EMP'PYE'MA (Neo-Lat., from Gk. ἐμπύημα, suppuration, from ἐν, en, in + πύον πυον, pus). An internal suppuration. The term is now applied specifically to a collection of pus in the pleura, but collections of pus in the accessory cavities of the nose, as the antrum of Highmore, or the frontal sinus, are also referred to as empyemas.

EMP'PYREU'MA (Neo-Lat., from Gk. ἐμπύρευμα, live coal preserved under ashes, from ἐμπυρεύειν, empyreúein, to kindle, ἔμπυρος, empyros, fiery, from ἐν, en, in + πῦρ, pyr, fire). The burned smell and acrid taste which result

when vegetable or animal substances are decomposed by a strong heat.

EMPYROMANCY. See DIVINATION.

EMS, ĕms, or **BAD EMS**, băt ĕms. One of the oldest and most famous watering places in Europe, situated in the Prussian Province of Hesse-Nassau, on the Lahn, about 8 miles from its junction with the Rhine, and 10 miles east-southeast of Coblenz (Map: Prussia, B 3). It lies in a charming valley surrounded by thickly wooded hills. Its many warm mineral springs, varying in temperature from 79° to 135° F., are considered especially efficacious in the treatment of diseases of the respiratory organs. The three springs discovered about 1865 and those opened since are all owned by the government. Ems is visited annually by over 12,000 patients and as many tourists. The Kurhaus, the older portion of which dates from the sixteenth century, contains the principal springs and baths. It is connected by an iron colonnade with the Kursaal erected in 1838, which contains reading rooms and concert halls. In Spiess Ems, the new quarter, are the Römerbad and the New Bath House. Many of the neighboring heights command extensive views of the Lahn valley, notably the Malberg on the left bank of the river. In the vicinity are important lead and silver mines. Pop., 1900, 6494; 1910, 6777. Ems was known to the Romans. In 1172 it came into the possession of the counts of Nassau. In 1866, with the Duchy of Nassau, it was united with Prussia. At Ems, on July 13, 1870, occurred the famous interview between King William of Prussia and the French Ambassador Benedetti, which precipitated the Franco-Prussian War.

EMS. A river in the northwestern part of Germany, rising in Westphalia, on the southwest slope of the Lippe Forest (Map: Prussia, B 2). It flows first in a westerly, then in a northwesterly, direction, entering Hanover, in which it flows north, and emptying into the North Sea, after a course of about 210 miles. The Ems drains an area of about 4600 square miles. Its chief affluents are the Aa, the Haase, the Hessel, and the Leda, all from the east. It is navigable for small vessels for only 25 miles from its mouth, but it supplies water to numerous canals, which are used for both irrigation and navigation. Nearly the whole of its course from Münster to Papenburg is paralleled by canals on the east side, while on the west connection is formed with the network of canals of Holland, and by the Dortmund-Ems Canal with the Westphalia coal region.

EMS, RUDOLF VON. See RUDOLF OF EMS.

EMSER, ĕms'ĕr, **HIERONYMUS** (1477-1527). A German Catholic priest. He was born at Ulm, studied at the University of Basel, and lectured at Erfurt, where Luther was one of his hearers. From 1505 he was secretary to Duke George of Saxony, who employed him to collect material regarding Bishop Benno of Meissen, and in 1510 sent him to Rome to obtain the canonization of that prelate. After the Disputation of Leipzig in 1519, he broke with Luther, although he had sympathized with a moderate reform. Luther was very violent against him, and he was particularly bitter against Luther's translation of the New Testament, which, he declared, contained 1400 lies and errors. In 1527 he published his rendering of the New Testament from the Vulgate, which is Luther's

adapted to the Vulgate text. In 1523 he translated into German the anti-Lutheran tract of Henry VIII. Emser's crest was a goat's head, and Luther delighted in calling him "Bock-Emser" and "Egoceros." Consult: Waldau, *Nachricht von Hieronymus Emsers Leben und Schriften* (Anspach, 1783); Kawerau, *Hieronymus Emser* (Halle, 1898); Enders, *Luther und Emser* (ib., 1890-92), containing his writings against Luther.

EMU, or **EMEU** (Portug. *ema*). A ratite bird of Australia, closely allied to the cassowary, but larger, sometimes weighing about 130 pounds, and next to the ostrich in size. It differs from the cassowary in having the bill horizontally depressed, the head feathered and destitute of a bony crest, and the throat nearly naked and with no pendent wattles. The feet are three-toed, as in the cassowary, and the wings are mere rudiments hidden beneath the loose filamentous feathers of the body. The color is dull brown, mottled with dingy gray; the young are striped with black. When assailed, emus strike backward and obliquely with the feet, like the cassowary, and they are so powerful that a stroke of the foot has broken a man's leg. They cannot fly, but run very fleetly. They are timid and peaceful and trust altogether to speed for safety, unless hard pressed. In a wild state they sometimes occur in small flocks, but they have now become extinct in the more thickly settled parts of Australia. The extinction of the genus will be prevented, however, by its being preserved in a state of domestication, as they are very easily domesticated and breed readily in that state. The flesh is rather tough for eating. The common emu has frequently been bred in Europe, where it is constantly seen in menageries or domesticated in English parks. The eggs are six or seven in number, dark green; the male performs the principal part of the incubation. The fat beneath the skin contains much oil; six or seven quarts are obtained from a single bird, and on this account it has been much hunted in Australia. Its food consists chiefly of roots, fruits, and herbage. Besides a drumming sound, which is frequently emitted, it gives forth a high-pitched piping note. It is probable that only one species of emu is living, *Dromæus nova-hollandiæ*. Several have recently become extinct. These constitute the family Dromæidæ, of which a fossil species has been discovered in the Tertiary deposits of India. Consult Matthew, *Birds of Australia*, vol. i (London, 1910-11). See PLATE OF CASSOWARIES.

EMU, or **EMEU WREN** (Australian *emu* + Eng. *wren*). A very small, brown, ground-keeping flycatcher (*Stipiturus malachurus*) of Australia, also called pheasant-tailed warbler. It is so named because of the great elongation of the central feathers of its tail, which are so loosely constructed as to resemble the plumage of the emu. The birds are described as flying with difficulty and preferring to creep about among herbage and low bushes near the ground like little field mice, where the male utters a weak but pretty song. Consult Campbell, *Nests and Eggs of Australian Birds* (Sheffield, 1900). See PLATE OF WRENS, WARBLERS, ETC.

EMULSIN (from Lat. *emulsus*, p.p., *emulgere*, to milk out, from *e*, out + *mulgere*, to milk). An enzyme found in plants, which decomposes various glucosides into glucose (grape sugar) and other products. It occurs in cer-

tain members of the rose family, notably in the almonds, both sweet and bitter, and the cherry laurel, in some spurge belonging to the genus *Manihot*, and in several common molds and lichens. Amygdalin, salicin, and other glucosides are split up by emulsin, which acts best in neutral solutions and at temperatures between 30° and 40° C. (86° and 104° F.). It is destroyed at about 80° C. (176° F.). See ENZYME; GLUCOSIDE; BENZALDEHYDE; DIGESTION IN PLANTS.

EMULSION (Fr. *émulsion*, from Lat. *emulgere*, to milk out). Emulsions are liquid preparations consisting of oily, fatty, resinous, or otherwise insoluble substances suspended in watery liquids by the intervention of gum, mucilage, or other viscid material called emulsifying agents. Natural emulsions comprise products of animal or vegetable origin, consisting of oily or resinous substances so combined with gum or albumin as to be readily miscible with water without separation. Milk and egg yolk are such typical emulsions, and seeds and gum resins form emulsions when triturated with water. Artificial emulsions are made by thoroughly mixing the oil with the emulsifying agent, adding a certain proportion of water and triturating the mixture in a mortar or agitating it in a flask. Volatile oils require the addition of a fixed oil to produce a stable emulsion. Water-insoluble substances—salicylic acid, chloroform, salol, etc.—may be emulsified in the same way as oil of turpentine, i.e., by the addition of gum tragacanth or acacia. In the United States Pharmacopœia six emulsions are official: of almonds, asafetida, chloroform, cod-liver oil, cod-liver oil with hypophosphites, and oil of turpentine.

ENALIDS (from Gk. *ἐν*, *en*, in + *ἄλς*, *hals*, sea). In botany, the members of the marine fixed vegetation (benthos) (q.v.) which grow attached to loose soil. Submerged eel-grass meadows form one of the chief enalid societies.

ENALIOSAURUS. See ICETHYOSAURUS; PLESIOSAURUS.

ENAMBUC. See ESNAMBUC.

ENAMEL (*en* + older form *amel*, Fr. *émaîl*; OF. *esmail*, It. *smalto*, from OHG. *smalz*, Ger. *Schmalz*, butter, from *schmelzen*, to melt, Gk. *μῆλειν*, *meldein*, to melt). A glaze coating applied by fusion to any substance which will bear the necessary heat, especially to metals and to pottery (q.v.). Enamel is really a kind of glass composed of silica, minium, and potash, to which the desired color is given by means of metallic oxides. It may be applied so as to cover the whole surface, and the new surface thus formed may be painted with vitrifiable colors, or the enamel may be applied to parts of the surface only, so that the colors of this partial application, combining with the colors of the object itself, may produce a decorative effect; and, finally, the enamel may be treated as a transparent or translucent mass, showing its color effect equally by transmitted and by reflected light. In each of these methods the enamel itself is provided in lumps or sticks or rods, each piece being usually of a separate solid color and having been previously vitrified. This material is ground very fine, mixed with gum water or some similar adhesive vehicle until it forms a paste, and can be applied with a brush. The object is then put into the enameling furnace, and in the heat the enamel passes from the condition of a dampened powder, through the state of flux or semifluidity, into a hard,

glossy, bubble-like mass looking very like the wet powder of its first condition.

Modern glass of brilliant iridescent surface is not generally enameled; but the glass lamps suspended in mosques throughout the Levant, and the glass vases, drinking vessels and the like, which are also of Saracenic or Moorish work, are decorated by enameling in the proper sense. The distinction is obvious to one who notes that in the Oriental pieces the body of the glass vessel shows between the usually opaque and projecting masses of the enamel which has been put on separately and fused and hardened separately. Similar work has been done in Europe, though rarely. So, in a porcelain vase decorated in colors, the painting which is applied over the glaze is of the nature of enameling and is easily seen to be an application made after the completion of the body of the vase. On the other hand, when a Chinese kettle or jardinière of thin metal is coated on both sides with a solid, opaque, uniform coating, giving it a finished look somewhat, but not quite, like that of porcelain, and when this hard and glassy surface is painted with flowers and the like, it is surface enamel of a kind very common in the Orient, though hardly used in European handiwork, except in connection with Limoges enamel, as mentioned below. These two methods of using the decorative quality of enameling are then distinguished as (1) that which covers the whole surface, and (2) that which is so applied to another surface as to form with it a kind of mosaic pattern.

Of the first kind, one variety has been described above; another is that usually known as Limoges enamel. In this the enamel is applied to a plate of metal with the express purpose of affording a ground for painting, and the paintings are often of very elaborate character. Thus, the work of the sixteenth century, in which are distinguished the names of Pénicaud, Jean Courteys, and Léonard Limousin, is famous for the use of completely developed painting of the figure, treated, of course, decoratively, i.e., without shadows and with the high lights often touched with gold, but with the figures completely modeled and the story completely told. At a later time these proper limitations of the art disappear, and the eighteenth-century Limoges enamel resembles very closely the work on paper or vellum, the slight relief being the chief distinctions. The tendency of the time was away from brilliant coloring, and much of the later Limoges enamel was painted in monochrome.

That enamel which forms a mosaic pattern relieved upon the background of the original substance may be on glass, as stated above, and then the glass is usually translucent, and the pattern, in several colors, with gold, is in opaque body and in slight relief upon it. When applied to ceramic ware, as Chinese porcelain, it is usually combined with blue underglaze painting and is lost in the general color effect. When it is applied to metal, this is done according to one of two methods—the cloisonné and the champlevé methods. Cloisonné work is that which is done by building up upon the metal surface very small partitions (*cloisons*), dividing up the field, as of copper, into little compartments; each of these compartments to be filled with enamel. Champlevé enameling is done by engraving out the solid surface so as to

leave little pools or hollows, which are to be filled with enamel. In either case a metal line or narrow space separates the pieces of enamel one from another. It is usual to grind the hard-finished enamel down until the glossy surface and the metal surface coincide and can be polished together. But in Oriental enamels it is not very uncommon to see a rougher and more picturesque treatment with the little compartments or hollows filled only in part, or else more than filled, so that considerable diversity of surface results. The very finest pieces of Oriental cloisonné enamel are of extraordinary brilliancy of decorative effect. The surface is very complete and perfect, with only minute bubbles to break its uniformity and only slight discolorations, as of pale-brown spots on the blue, to give its color some additional vivacity. Each compartment may be of solid, uniform color, or may itself contain a gradation, as of red passing slowly into white. The finest in color are Chinese, of the sixteenth or seventeenth century of our era. Very recent Japanese pieces show the partitions reduced almost to nothing—very slender and of no separate effect, the color masses of the enamel seeming to touch; whereas in old Chinese work they might be $\frac{1}{4}$ of an inch wide and present even broader surfaces where several strips met and were secured together.

A highly artistic variety of enamel is the so-called *basse taille*, in which the metal, usually gold or silver, is carved in a very low relief, and a transparent enamel is fused to the incised portions. This may be defined as cloisonné with the metal ground removed, and hence a transparent enamel. See NIELLO.

History. The art of enameling was practiced among the most ancient of civilized peoples. The Egyptians and Babylonians used enameled bricks of wonderful clearness and lustre for the decoration of whole apartments of their palaces, as may still be seen in the palace of Rameses III at Tel el-Yehudia and that of Nimrod recently excavated in Babylon. The Egyptians also used cloisonné enamel in their exquisite jewelry. The Greeks preferred cloisonné in their jewelry and other objects of decorative art and as an accessory to the noblest works of sculpture, as in the embroidery of the draperies of the Olympian Zeus by Phidias. Its use in jewelry, etc., was continued by the Romans, but it was reserved for the Byzantines to become the greatest masters of cloisonné. With the skill of design equalled only by a sense of color, they used it for a multitude of ecclesiastical objects—missal covers, shrines, tabernacles, crosiers, chalices, ciboria, crosses, and the like. The ground was of gold, which explains why so few examples survive, and simple colors, opaque and of dull finish, were preferred; the design was purely decorative. The art was practiced as early as the reign of Justinian, and, although interrupted by the iconoclastic movement, the development attained new splendor in the ninth and tenth centuries and lasted until the downfall of the Empire. The most magnificent example of Byzantine enamel is the well-known Pala d'Oro (q.v.) in St. Mark's, Venice.

Among Western nations champlevé was the principal variety of enamel used. The Celtic tribes seem to have been especially skilled, and during the early Middle Ages the Irish in particular wrought beautiful ecclesiastical objects, as may be seen in the Dublin Museum. The earliest important centre of the art on the

Continent was Cologne, where a school flourished during the tenth, eleventh, and twelfth centuries. Its works are scattered throughout the Rhinelands and may be studied in such noble examples as the Shrine of the Magi in Cologne Cathedral, and the altar front at Klosterneuburg by Master Nicolas, of Verdun. From Cologne the art was probably transplanted to Limoges, which attained great importance in the second half of the twelfth century and remained the principal centre of the art of enamel in western Europe throughout the Gothic period. Fine examples may be seen in the several shrines (chasses) of the Morgan collection, New York. Limoges was also the principal centre of enamel painting (properly so called) of the fifteenth, sixteenth, and seventeenth centuries, described above. In the early fourteenth century the Italians invented the so-called basse-taille enamel, of which there is a fine example, the "King's Cup," in the British Museum.

Among the Oriental nations China has produced cloisonné ware of a distinctly national character, comparable in beauty and splendor to that of Byzantium. The art was not a native one, but was introduced from Constantinople by the Mongols in the North and the Arabs in the South as intermediaries. It attained its most perfect development under the Ming dynasty (1368-1643), especially during the reign of Ch'ing-t'ai (1450-56); but splendid examples were produced in the Manchu period, particularly during the reigns of K'ang-hsi (1662-1722) and Ch'ien-lung (1736-95). It was used not only for the adornment of the vessels required by the temple service, but also in vases, bowls, and a variety of other objects of secular use.

A revival of the art of enameling took place in the late nineteenth century. The artist now has at his command better and more varied colors, purer metals, and more perfect appliances for the application of heat; but it cannot be said that the art has as yet equaled its past excellence. It is still used in connection with jewelry and other decorative work, but more frequently in enamel painting. Among the enamel painters of recent times are Claude Popelin, Grandhomme, and others in France, Bastanier in Berlin, Mach in Vienna, and Hubert Herkomer and Alexander Fisher in England.

There are good collections of enamels in the museums of decorative arts in London, Paris, Berlin, St. Petersburg, and other centres. One of the finest in existence is in the J. Pierpont Morgan collection—rich in rare Byzantine cloisonné, German and Limoges champlevé, as well as in the painted enamels of Limoges. The Brooklyn Institute Museum, New York, has a remarkable collection of Chinese cloisonné, presented by S. P. Avery.

Enamel in Industry. In the purely utilitarian employment of enamel its purpose is to protect the surface to which it is applied from oxidation or the action of corrosive substances. The earlier enameled ware was usually thick, but enamel is now successfully applied to sheet iron and sheet steel. The utensils are pressed out of the sheet metal according to the process described under DIES AND DIE SINKING and under HOLLOW WARE. The metal foundation having been properly prepared by annealing to stand the heat, it is dipped in the melted glaze and fired in an oven similar to that employed for

the glazing of pottery, which is kept at a temperature of about 1500° F. The constituents of the glaze and their proportions vary in the different factories and are carefully guarded trade secrets. The color of enameled ware is determined by the metallic oxides used in the glaze and does not materially alter the character of the enamel, although a pure white enamel is likely to be less tough than gray. The quality of the enamel depends not only on the character of the glaze, but also upon the number of coats applied. By one process four successive coats are applied, the first three of which are simply dried, while the fourth is burned at 1500° F. In another, two successively fused coats are applied. In the cheaper grades of enamel ware arsenic is said to be used in place of the oxide of tin, thus . . . the cost, according to the statement of a leading manufacturer, by 75 per cent. Agateware is simply a trade name for a variety of enameled ware, so called on account of its mottled appearance. Enameled ware, even of the highest grade, is likely to be injured by excessive heat, which, by making the iron expand faster than the glaze, cracks the latter. It is also liable to be affected by acids wherever there is the slightest break in the continuity of the surface of the enamel. When once acid penetrates the surface so that it can act on the iron underneath, it will gradually undermine the glaze so that it peels off.

ENAMELED CLOTH. A material used as a substitute for leather in making traveling bags covering upholstery and the like, and also for covering boxes. The process was invented in Newark, N. J., in 1849. It consists in covering cotton cloth with repeated coatings of a composition consisting of linseed oil, lampblack, resin, and other ingredients. The cloth is passed between heavy iron rollers, from one of which it

receives the coating of composition; sometimes this is spread by passing the cloth under a knife. Between the successive coatings (five or six in number) the cloth is dried and rubbed down with pumice stone, and after the last coat it is varnished. Last of all, the cloth is often passed through rollers, one of which has a surface that it stamps the material with indentations. Enamel cloth is somewhat similar to oilcloth in its method of manufacture, but it is much lighter, more flexible, and put to very different uses.

ENAMEL OF TEETH. See **TEETH**.

ENAMEL PAINT. See **PAINTS**.

ENARE, ä-nä'rä, or ENARA. A lake in the Finnish government of Uleåborg, not far from the Norwegian frontier (Map: Russia, Cal). It covers an area of nearly 550 square miles and receives a number of tributaries, including the Ivalo. Its outlet, the Pasvik, empties into the Arctic Ocean and forms partly the boundary line between Russia and Norway.

ENAREA, ä-nä'rë-ä. A hilly region of Abyssinia, between lat. 7° and 9° N. (Map: Africa, H 4). Its population is about 40,000. Capital, Saka.

ENARGITE. A sulpharenide of copper, sometimes occurring in black metallic, orthorhombic crystals, but more commonly in granular masses. It is found associated with other copper minerals in Chile, Peru, and Mexico, also in South Carolina, Colorado, Utah, California, and in the Tintic district of Montana. It is much used as an ore of copper.

ENARTHROSIS (Neo-Lat., from Gk. ἐνάρθρωσις, ball-and-socket joint, from ἐν, en, in + ἄρθρον, arthron, joint). The term used by anatomists to express the kind of joint (q.v.) which admits of the most extensive range of motion. It occurs in the hip and shoulder joints.

ÉNAULT, ä'nô', LOUIS (1822-1900). A French author, born at Isigny (Calvados). He wrote a large number of novels and books of travel, e.g., *Pèlemêle* (1862); *Stella* (1863); *Olga* (1864); *Le baptême du sang* (1873); *Nadège* (1895); *Myrio* (1898). He made the French translation of *Uncle Tom's Cabin* (1853).

ENCÆNIA, or ENCENIA (Lat., from Gk. ἐγκαίνια, enkainia, from ἐν, en, in + καίνος, kainos, new). Dedication festivals held in early Christian times to consecrate a new church or a heathen temple to Christian use and later repeated on the anniversaries of such occasions. At first they were simple, but by the beginning of the seventh century they had come to have the character of a fair with booths, dramatic representations, singing, and dancing. They were disapproved by the Council of Chalons (650). The name is also applied to the festivals held by the University of Oxford, in June, in honor of its founders and benefactors. See **COMMEMORATION**.

ENCAMPMENT. During active operation in the field troops are generally quartered in tents. The principal tents in use in the United States are the shelter, just large enough for two men to sleep under and separable into two parts, each carried by one of the soldiers on the march; the small pyramidal, with a floor space of about 9 × 9 feet; the large pyramidal, 16 × 16 feet; the hospital, 14 × 14½ feet; and the storage, 17 feet, 10 inches by 20 feet, 5 inches. In putting tents up in rows a space between the tents at least half the width of the tent should be left for the guy

ropes and passages. Unless the soil is unusually porous, small trenches should be dug around each tent to carry off rain water, which might otherwise make the tent uninhabitable. The

U. S. A. COMMON TENT

floors of the tents should ordinarily be raised above the ground. The laying out of shelter-tent camps can be effected as a matter of drill and without any special staking out of the camp.

Types of arrangement for a camp for each of the arms and for an infantry division are shown in the Regulations. That shown in the accompanying cut is suitable for the infantry:

A simple way of laying it out quickly is with the eye to stake out the line of the front of the company officers' tents, beginning at one end of the line and laying off lines at right angles to this for the front of the living tents of the men. The position of the front tent poles for the latter tents can then be indicated by pacing, or by stretching a string having knots at the proper intervals. The company streets should, if possible, be at least 20 paces wide in the clear. If the camp is to last more than a few days, and the requisite ground is available, space is left for mess tents near the company kitchens. The hospital should be located, if possible, on a particularly healthful site, as far removed as is convenient from the living tents. The guard tent is placed on the line of sentinels conveniently for general access to the camp from the neighboring road. Arranged in this manner the camp for a regiment of infantry can be crowded into 10 acres; if ground is available, it is better to utilize more space. A cavalry camp is arranged on a similar plan, with the addition of provision for the horses. These are placed generally either in the prolongation of the company streets beyond the latrines or between companies. While a large camp lends itself to comfort and sanitation, it has the disadvantage of increasing the guard and police duty. In the presence of the enemy, camps and bivouacs must be modified to afford the best protection for men, animals, and trains.

Where troops have remained in one site for a long period in cold weather, log and board

huts have been constructed for their occupancy. In selecting a site for a camp there is frequently little latitude, but wherever practicable it should be placed in a healthy location, especially avoiding everything in the nature of a marsh. It is essential to encamp within reasonable distance of a water supply and desirable to be near fuel and grass. As a rule, provision should be made for not less than five gallons of water for each man, and 10 gallons for each animal, in the camp. On going into camp efficient arrangements should be effected for the protection of the water supply and for distributing it to the men and animals. If a source of supply is to be used for a considerable time, particularly if animals are to be watered there, an area should

WATER FILTERS, BRITISH ARMY PATTERN.

be drained and paved to prevent the ground from becoming muddy. Where the supply is scanty, tanks should be constructed for catching the water at night and at other times when it is not being consumed. Where the best water obtainable is impure, it should be boiled or chemically treated and filtered—if practicable, through filters carried by the troops, otherwise by temporary ones constructed of sand, gravel, and charcoal. Where transportation is available, well augers, well points, canvas water bags, barrels, and pumps should be carried. For cooking, United States troops are provided with field ovens, which are supplemented by small fire-places in the ground. See FIELD COOKING.

The physical problems connected with encampment vary with the nature of the country and the season of the year. Among the most important are those relating to the disposition of the refuse matter. No general rule can be given covering this, excepting that all trash and garbage should be removed completely from the site, either by transportation or by burning. Fuller details on these subjects will be found in Beach, *Manual of Military Field Engineering* (Kansas City, 1896); Fieberger, *Manual of Field Fortification* (New York, 1901); *Field Service Regulations*, United States Army (Washington, 1914); *Infantry Drill Regulations*, United States Army (1911); and the *Chatham Text-Book in Military Engineering* (London, 1894). See CAMP; CAMP EQUIPAGE.

ENCAUSTIC PAINTING (Lat. *encausticus*, Gk. *ἐγκαυστικός*, *enkaustikos*, burnt in, from *ἐκαλεῖν*, *enkaiein*, from *ἐν*, *en*, in + *καλεῖν*, *kaiein*, to burn). A method of painting practiced by the ancients, especially by the Greeks, in which the colors were mixed with wax and resin and softened by aid of fire. Some Greek portraits have come down to us, but no important specimens of Greek encaustic painting other than these are known to be extant, and it is an art the secret of which is largely lost. The cauterizing

or heating of the painting after completion rendered the colors more brilliant than tempera or fresco. Pliny describes three processes of encaustic painting used by the Greeks and Romans. In the one most commonly practiced the wax colors were spread within determined outlines by means of a spatula. Both the spatula and colors were heated in a brazier standing beside the painter. As practiced by the ancients, encaustic painting retained its integrity of color for a longer period than any other medium known to the painted arts. The "Battle of Marathon," painted by Polygnotus, was preserved under an open portico at Athens for more than 900 years. Some of the mural paintings in Pompeii are encaustic; and very interesting survivals are the Greek portrait panels from the Fayum (Egypt), usually on wood and generally used as a covering for the heads of mummies. The Metropolitan Museum, New York, possesses a number of good examples, together with the spatula and implements used in the process. As early as the middle of the nineteenth century experiments were made to revive encaustic painting, and this was continued during the century; but nothing satisfactory has as yet been perfected. One of these modern methods, that of Fernbach (1793–1851), was used in the decoration of the Hohenstauffer Hall of the Royal Palace in Munich. Consult Thomas, *Methods of Mural Decoration* (London, 1869); Cros and Henry, *L'Encaustique et les autres procédés de peinture chez les anciens historique et technique* (Paris, 1884); Donner von Richter, *Ueber Technisches in der Malerei der Alten, insbesondere in der Enkaustik* (Munich, 1885); Laurie, *Greek and Roman Methods of Painting* (Cambridge, 1910).

ENCAUSTIC TILES. See TILES.

ENCEINTE, *ân'sânt'* or *ân'sânt'* (Fr. inclosure). A term in military engineering and fortification, used to denote the area within the principal encircling wall of a fortified place. See FORTIFICATION.

ENCEL'ADUS (Lat., from Gk. *Ἐγκέλαδος*). In Greek legend the son of Tartarus and Gæa. With the other hundred-handed giants he made war on the gods, but was slain by Zeus and buried under Mount Etna. (See GIANTS.) Earthquakes were explained as the results of his movements as he tried to free himself, and the flame of the mountain was regarded as his fiery breath. Consult Longfellow, *Enceladus*, and King *Robert of Sicily*.

ENCENIA. See ENCENIA.

ENCEPH'ALAR/TOS. A genus of African cycads, including about 12 species. See CYCADACEÆ.

ENCEPHALOCLE, *ên-sêf'á-lô-sêl* (from Gk. *ἐγκέφαλος*, *enkephalos*, brain, from *ἐν*, *en*, in + *κεφαλή*, *kephalê*, head + *κῆλη*, *kêlê*, tumor). The term applied to a tumor projecting through the skull, in one of the parts where the bones are incomplete in infancy, and consisting of a protrusion of the membranes of the brain, containing a portion of brain itself. The most common situation of such tumors is in the middle line, more often in the frontal than in the occipital region. Some of these cases can be cured by surgical measures.

ENCHIRIDION, *ên'ki-rid'i-ôn* (Lat., from Gk. *ἐγχειρίδιον*, *encheiridion*, handbook). A manual compiled by Arrian containing a digest of the teachings of the Stoic philosopher Epictetus (q.v.).

ENCHONDROMA, ěn'kōn-drō'mā (Neo-Lat., from Gk. *en*, in + *chōndros*, *chondros*, cartilage). The term employed in anatomy to signify an abnormal growth. These growths most commonly occur in connection with the bones, and they are not infrequent in some of the glandular structures. See **TUMOR**.

ENCINA, ěn-thē'nā, **JUAN DEL** (?1469-?1529). The father of the Spanish drama, supposed to have been born at the village of La Encina, near Salamanca, at the university of which he is said to have been educated. He is also supposed to have been present at the surrender of Granada. In 1492, also, he entered the household of the Duke of Alba and soon after began to entertain his patrons with original comedies, in some of which he himself took part. In 1498 he went to Rome, where he became maestro di cappella to Leo X. Afterward he took orders, celebrated his first mass at Jerusalem in 1519, and after his return to Rome was appointed prior of the monastery of León. He is supposed to have died at Salamanca. Of Encina's poems, more than 170 lyrics have survived, many of them with musical settings by their author. More interesting than any of these, however, are the 14 plays, which are classified as *églogas*, *representaciones*, and *autos*, which differ from one another in little except name, being all presentations of extremely primitive themes, the subject of which is sometimes sacred and sometimes not. He is chiefly interesting as marking the transition from the purely religious to the secular stage and as exhibiting, in embryo at least, nearly all, if not indeed absolutely all, of the *genres* that were developed in the course of the great sixteenth and seventeenth centuries. The best edition of his works is that of Francisco Asenjo Barbieri, *Teatro completo* (Madrid, 1893). The lyrics (68 of them), with the author's own music, appear in Francisco Asenjo Barbieri, *Cancionero musical de los siglos XV y XVI* (Madrid, 1894). Consult also R. Mitjana, *Sobre Juan del Encina, músico y poeta* (Málaga, 1905); M. Menéndez y Pelayo, *Antología de poetas líricos castellanos*, vol. vii (Madrid, 1898); E. Cotarelo y Mori, *Estudios de Historia Literaria de España* (ib., 1901); R. Mitjana, *Cancionero de Uppsala* (Uppsala, 1909); E. Díaz Jiménez y Molleda, *Juan del Encina en León* (Madrid, 1909).

ENCISO, ěn-thē'sō, **MARTÍN FERNÁNDEZ DE**. See **FERNÁNDEZ DE ENCISO**, **MARTÍN**.

ENCKE, ěn'ke, **ERDMANN** (1843-96). A German sculptor. He was born in Berlin and studied at the academy in that city and with Albert Wolff. Several fine pieces of statuary in the German capital were designed by him, among them the following: "Friedrich Ludwig Jahn," bronze statue (Hasenheide); "Frederick I, Elector of Brandenburg" (façade of town hall); "Queen Louise of Prussia" (Thiergarten); a charming group of the Electress Elizabeth of Brandenburg and her son Joachim (National Gallery); and the sarcophagi of Emperor William I and Empress Augusta in the mausoleum at Charlottenburg. His works combine the severity of form of the Rauch school with a healthy realism and a touch of poetry and romance. He also executed a number of important bronze portrait busts, in which he used polychromy with success. He was appointed a professor of the Berlin Academy in 1883.

ENCKE, **JOHANN FRANZ** (1791-1865). A German astronomer, born in Hamburg, where his

father was a clergyman. After studying at Göttingen, under Gauss, he took part in the campaign of 1813-14 and in 1815 served in the Prussian army as lieutenant of artillery. On the establishment of peace he left the service and became assistant, and afterward principal, astronomer in the observatory of Seeberg, near Gotha. In 1825, chiefly at the instance of Bessel, he was called to Berlin to become secretary of the Academy of Sciences and director of the observatory. While at Gotha the astronomical prize offered by Cotta was awarded to Encke by the judges, Gauss and Olbers, for his determination of the orbit of the comet of 1680. This led him to investigate another problem, viz., the determination of the distance of the sun from the earth. Encke's results, based upon the two transits of Venus, in 1761 and 1769, were published in two separate tracts, entitled *Die Entfernung der Sonne* (1822-24). His best-known work, however, is his discussion of the orbit of the comet discovered by Pons, Nov. 26, 1818, which has a short period of about 1200 days, and which has since gone by the name of Encke's comet and has appeared regularly. (See **COMET**.) Encke's researches on this subject are contained in the transactions of the Berlin Academy. He endeavored to explain a remarkably regular change in the comet's period of revolution as the result of some resisting substance in the space traversed by the comet. There is, however, much doubt among astronomers as to the correctness of this hypothesis. In 1830 he undertook to edit the Berlin *Astronomisches Jahrbuch*, in which he published a number of astronomical papers. He issued four volumes of *Astronomische Beobachtungen auf der Sternwarte zu Berlin* (1840-56). His scientific writings were collected and published under the titles *Astronomische Abhandlungen* (3 vols., Berlin, 1868) and *Gesammelte mathematische und astronomische Abhandlungen* (3 vols., ib., 1888-89). Consult Bruhns, *Johann Franz Encke* (Leipzig, 1869).

ENCRATITES, ěn'krā-tīts (Lat. *Encratitæ*, Gk. *Ἐγκρατῖται*, *Enkratitai*, from *ἐγκρατής*, *enkratēs*, self-controlled, from *en*, in + *κράτος*, *kratos*, power). The name of early ascetics in the Christian Church. They arose at Rome about 172 and were numerous in Asia Minor. Their head and leader was Tatian (q.v.). They forbade marriage, the eating of the flesh of animals, and the use of wine, some going so far as to substitute water for wine in the Eucharist. They were found as late as the fourth century.

ENCRINAL, or **ENCRINITAL**, **LIME-STONE**. A name given to some limestones, from the great abundance in them of the calcareous fragments of crinoidea (q.v.), whole masses of the rock being almost entirely composed of them. There are large beds in the Hamilton and Helderberg groups in New York State.

ENCRINITES. See **CRINOIDEA**.

ENCYCLICAL LETTERS (from Lat. *encyclo*, from Gk. *ἐγκύκλιος*, *enkyklios*, circular, from *en*, in + *κύκλος*, *kyklos*, circle). A term denoting, in a general sense, circular ecclesiastical letters, whether from a council, bishop, or pope. In the early Church the letters sent by the members of a council to all the churches, or by a bishop to all the churches of a particular district or diocese, were so called; but the term is now applied exclusively to letters addressed by the Pope to all the bishops of the Roman Catholic church, which usually contain injunctions

and warnings against dangers which may threaten the church. One of the most remarkable encyclicals was that issued by Pius IX in 1864, accompanied by a syllabus in which he condemned 80 alleged errors in modern ideas of religion and civilization. His successor, Pope Leo XIII, issued a number of them on such subjects as Socialism, Bible study, capital and labor, and the reunion of Christendom. Pius X issued several of importance, including that in which he defined and condemned modernism (1907).

ENCYCLOPÆDIA (Gk. ἐγκυκλοπαιδεία, *enklyklopaideia*, a barbarous derivative of the Greek phrase ἐγκύκλιος παιδεία, *enklyklios paidēia*, circular, complete education). Originally the entire group of studies which every free-born Greek youth was required to complete in preparation for active life—the liberal curriculum. In this sense the Greek phrase was adopted by the Romans. Its signification, however, was early widened, both in Greek and Roman usage, to include systematic study of, or instruction in, all the branches of learning—of the entire “circle” of the arts and sciences, or of a special group of them; and this remained its dominant meaning until a comparatively recent time. At present it survives chiefly in the technical use of the word in systematic theology and philosophy to designate the investigation of the relations of the various special subjects which those disciplines include. With this idea of “encyclic” education was also soon associated the notion of collecting the materials of such instruction into a single work, in which the contents and relations of the various arts and sciences should systematically be expounded. Attempts to produce books of this kind were made at an early date, though the name “encyclopædia” was not given to them until the 17th century. This is now its common application.

What has been said of the origin of the word explains also its characteristic of the earliest encyclopædies. They were treatises or groups of connected treatises adapted for continuous reading and study and not mere repositories of knowledge. They were designed to serve rather as all-comprehensive textbooks than as works of reference in the modern sense of that phrase. And their substance corresponded to their form, for they contained for the most part simply the more or less extensive accumulations of learning made by their authors individually, and bore no resemblance to the products of coöperative scholarship which the enterprise of the modern publisher has made familiar. This type of encyclopædia, with various modifications, prevailed for many centuries and has not yet entirely been abandoned. The first is said to have been compiled by Speusippus (died 339 B.C.), a disciple of Plato; but of his work in this line nothing is known. Among the Romans, Marcus Terentius Varro (died about 27 B.C.) was the first of the encyclopædists, and his *Disciplinarum Libri IX* (Nine Books of Studies) exemplifies well the above-explained connection of the encyclopædia with the liberal curriculum. It was an encyclopædia of the liberal arts—grammar, dialectic, rhetoric, geometry, arithmetic, astrology, music, medicine, and architecture—in nine books, each devoted to one of these special subjects. His *Antiquitates Rerum Humanarum et Divinarum*, in 41 books, dealing with Roman antiquities, civil and re-

ligious, was of a similar character. Neither of these works has survived. The famous *Historia Naturalis* of Pliny the Elder (23-79 A.D.), the earliest of the encyclopædic compilations of antiquity which we possess, approaches more nearly to modern works of the kind in material, but in form does not differ essentially from its predecessors. It is an encyclopædia of natural science, considered especially with reference to human life, and, accordingly, includes geography, medicine, and the history of art. The topics treated in its 37 books comprise the mathematical and physical description of the world, anthropology and human physiology, zoology, comparative anatomy and physiology, botany (including agriculture and horticulture), medicinal zoology, and mineralogy (together with the use of the metals and of precious stones in the arts). It is a mass of facts, often ill digested, collected from a large variety of sources, and is an inexhaustible storehouse of information. About four and a half centuries later Martianus Capella, a native of north Africa—probably of C. . . .

. . . . an encyclopædia of the seven liberal arts, which in the Middle Ages was extensively used as a textbook in the schools, and which departs even further than those above mentioned from the modern ideal. It is partly in prose and partly in verse, resembling in this the *Satura Menippea* of Varro and the *Satyricon* of Petronius; hence the names *Satura* and *Satyricon* have been given to it. *Satura* (satire) personified is also represented by the author as having inspired the work. Its theme is the marriage of Mercury with “a very learned maiden” (*doctissima virgo*), Philologia (philology), on the advice of Apollo, and the various forms of learning (personified) are introduced in the bridegroom's train. Though for centuries highly esteemed, it is now notable chiefly from the fact that in it the revolution of the planets Mercury and Venus about the sun, and not about the earth, is asserted in a passage which may have suggested to Copernicus his theory of planetary motions. A more important work in 20 books (unfinished), entitled *Etymologiarum (Originum) Libri XX*, with a similar aim, was compiled by Isidore, Bishop of Seville (about 570-636). It deals with the seven liberal arts—medicine, animals, the earth, Old Testament antiquities, etc.—and was long deservedly held in high repute. The tenth book, which is etymological in contents, is arranged alphabetically. Isidore's encyclopædia was rearranged in 22 books, and otherwise edited in the ninth century, under the title *De Universo Libri XXII, sive Etymologiarum Opus* (also known as *De Natura Rerum, De Origine Rerum*, etc.), by another ecclesiastic, Rabanus (or Hrabanus) Maurus (c. 776-856), Archbishop of Mainz. Much of Isidore's material was omitted, and Rabanus' work as a whole shows no advance beyond that of his predecessor. From about the middle of the eleventh century dates a short encyclopædic work in Greek, written in the form of questions and answers, by Michael Constantinus Psellus the younger (born 1020, died after 1105), entitled *Διδασκαλία παντοδαπή*. It treats of divinity, natural history, and various special topics. A more important Greek work, probably of a somewhat earlier date (though it contains quotations from Psellus which may be original), is the dictionary that bears the name of Suidas, about whom nothing is

known. This is a lexicon, in general alphabetically arranged; but it contains, besides definitions of terms, a good deal of biographical, geographical, and historical information, thus suggesting an important characteristic of the modern encyclopædia and also foreshadowing the encyclopædic dictionary of a very recent time. It is an uncritical compilation, but is still very important as a source of information about the literatures and languages of antiquity. A number of valuable critical editions of it have been issued. But the most important of all these early encyclopædias is the great *Bibliotheca Mundi*, or *Speculum Majus*, or *Speculum Triplex* (as it is variously entitled in the manuscripts), of Vincent of Beauvais, a Dominican friar of the thirteenth century. It is a product of indefatigable labor and vast erudition and sums up the learning of its time. It consists of three parts: *Speculum Naturale*, in 32 books, consisting of an account of the creation and the material world, under a great variety of topics; *Speculum Doctrinale*, in 17 books, comprising language (with a dictionary of considerable length), grammar, logic, rhetoric, theology, physics, etc.; and *Speculum Historiale*, in 31 books, consisting of a history of the world from the creation down, with a prophetic forecast of the future, which covers the end of the world (placed in 2376 A.D.), the reign of Antichrist, the Last Judgment, and the renewal of all things. To these a fourth part, *Speculum Morale*, was added by another hand. The author entitled his work *Speculum* (mirror) because, as he said, it reflects everything in the visible and invisible worlds which is worthy of notice—as, indeed, it fairly does for its age. It is professedly a compilation from the earlier literature and is especially valuable for its references to authors. From this time on encyclopædic works of this ancient, discursive, and pedagogical character become more and more numerous, but only the most important are mentioned: Between 1260 and 1270, Giovanni Latini (1230–94), a native of Florence, wrote in French *Li livres dou trésor*, a summary of the various departments of philosophy, in the wide sense then assigned to the word. It consists of three books, of which the first treats of the creation, the history of the Old and New Testaments, primitive governments, natural science, and natural history; the second of morals, consisting mainly of translations from the *Ethics* of Aristotle and a popular work called the *Moralities of the Philosophers*; and the third of instruction in rhetoric and of civil government as practiced in the Italian states of that period. This third book is particularly interesting, and the entire work is still valuable in many ways. It was printed in 1474 and several times reprinted. A critical edition of it, by a special commission, was designed by Napoleon I, but the plan was not carried out. In 1550 was published the *Encyclopædia seu Orbis Disciplinarum tum Sacrarum tum Profanarum Epistemon* of Paul Scalich—a survey of the entire circle of science, sacred and profane, notable as the first book to which the title “encyclopædia” was given. In 1630 appeared the *Encyclopædia Septem Tomis Distincta* of Johann Heinrich Alsted (1588–1638), in seven volumes (divided into 35 books), designed to be a methodical summary of all the sciences, and which, though falling far short of its aim, merited the high reputation which it long enjoyed. The second volume contains lists of Hebrew, Syriac, Arabic, Greek, and Latin words

defined in Latin. Lastly, the most extraordinary example of the ancient type is *La science universelle* (1663) of Jean Magnon, an encyclopædic poem designed to fill 10 volumes of 20,000 lines each, but incomplete.

All of the above-mentioned books, and many of their successors in the same class, were more or less unsystematic, or even chaotic, in form and crude in substance. The problem of coordinating or systematizing all the branches of science, which they in some measure at least sought to answer, was, however, a legitimate one, and the attempt to solve it was frequently repeated down to recent times. Bacon's (incomplete) *Instauratio Magna* has been reckoned as the first of these attempts to be made with adequate method and upon genuine philosophical principles. But that work can scarcely be described as encyclopædic, even in this sense. More obviously within this class are numerous works, chiefly German, which appeared mainly in the eighteenth and nineteenth centuries, and which were for the most part written from the point of view of some particular philosophical system, especially the Wolfian, Kantian, and Hegelian. Such, e.g., are *Lehrbuch der Wissenschaftskunde* (1772), *Mug's Versuch einer systematischen Encyclopædie der Wissenschaften* (1796–98); Schmidt's *Allgemeine Encyclopædie und Methodologie der Wissenschaften* (1810); Georg Wilhelm Friedrich Hegel's *Encyclopædie der philosophischen Wissenschaften* (1817).

The transition from this ancient type to the modern was due to a change in form which occurred about the middle of the seventeenth century, and which originated, doubtless, in the desire to make books of this kind more easy of consultation. This change was from the more or less logical arrangement of the material by subjects to its alphabetical arrangement by key words, names, or special topics. In other words, the encyclopædia was assimilated to the dictionary, and from that time on the word “dictionary” (or “lexicon”) has been freely used as the title of encyclopædic works. The change, moreover, was not confined to the form, for the alphabetical arrangement inevitably led to (if its adoption did not spring from) a change in the purpose and character of encyclopædic compilation, viz., that from the exposition of the system of human knowledge to the mechanical arrangement of its contents. The encyclopædia became, in this line of its development, a work of reference in the strict sense of that word—a work for occasional use, in which any particular topic or item of information desired can be found under the proper word in an alphabetical vocabulary. This practical aim and this method—which, as was said above, were exemplified by the *Lexicon* of Suidas—have, however, been adopted by modern encyclopædias in varying degrees. On the one hand, there has been a tendency to approach more and more closely to the dictionary type by increasing the number and variety of the vocabulary words (topics) and correspondingly subdividing the material contained in the book; and, on the other, a tendency (in which the influence of the ancient systematic type is obvious) to restrict the vocabulary and combine the material as much as possible under comprehensive titles. In its extreme form the former tendency has given rise to the modern “encyclopædic dictionary” and such works as the *Grand dictionnaire universel du XIX^{ème} siècle* of Pierre Larousse (for both see below), and the latter to encyclopædias which are

little or nothing but aggregations of monographs. These two types—subdivision of material and the collection of it in monographs—are distinct, though no very exact classification of existing encyclopædias can be based upon them, since most of them conform in varying degrees to both. It may be said, however, that encyclopædia makers incline in practice, as well as in theory, more and more towards the adoption of the dictionary type, as better suited to the practical needs of scientific and literary workers and as, in fact, essential to the adequate presentation of the vast accumulations of modern science, history, and biography. In the development of this movement the distinction between the dictionary and the encyclopædia has occasionally been obliterated by the inclusion in the headings of the latter of too many of the common words of the language; it is generally recognized, however, that this should be restricted to those words which can properly be made the theme of encyclopædic articles rather than of mere definitions. As regards the material included in modern works, no general statement can be made that would not be subject to numerous exceptions. Some pay most attention to the sciences and arts, others to history, geography, biography, etc. Others are restricted to some one subject or special group of subjects. During the last three decades a very large number of the special encyclopædias have appeared. Another important characteristic of modern methods is the employment of a large corps of specialists, both as compilers and as editors. Some degree of coöperation of this kind is found in many of the encyclopædias of the seventeenth and eighteenth centuries, notably in the great work of Diderot and D'Alembert (for a description of which see below); but in the nineteenth century it was developed into an elaborate system, necessitated especially by the rapid advance and multiplication of the special sciences. No good general encyclopædia, at least, is now possible which does not include in its editorial staff a small army of men of science, historians, theologians, lawyers, and so on. The aim of its projectors, in a word, is to collect, at first hand, the special knowledge of the time and to present it in a manner that is acceptable to specialists. That this ideal is not always realized need not be said. Lastly, the use of pictorial illustrations—plates and diagrams, and pictures in the text, which found a place in encyclopædias at an early date—has been extended, and their quality has, as a rule, been improved.

The first notable encyclopædia of this class is *Le grand dictionnaire historique, ou le mélange curieux de l'histoire sacrée et profane* (1674) of Louis Moréri (1643–80), in form a special dictionary of history, mythology, genealogy, and biography. It was frequently reissued, was revised and enlarged by various hands, and was translated into English, German, Spanish, and Italian. Moréri's work was marred by many imperfections, and the changes made by its successive editors left little of the original intact. Among those who undertook the labor of correcting its defects was Pierre Bayle (1647–1706), whose *Dictionnaire historique et critique* (2 vols., 1695–97) is the most famous encyclopædic work of the seventeenth century. A second edition, in three volumes, was published in 1702, under the author's supervision; the third (1720), in four volumes, edited by Prosper Marchand, is one of the best. It was subse-

quently often reissued and was translated into English twice (first from the second edition and later from the fifth) and into German. It was in its time an exceedingly valuable book and is still worth consulting. By the simplicity and clearness of its style and its engaging literary qualities it won a permanent place in the history of literature as well as in that of lexicography. Especially notable is its skeptical tone, which made it the object of much theological animosity. Bayle, in fact, changed his religion twice and naturally was not much loved either by Protestants or Catholics. At the same period an encyclopædia of the dictionary type, entitled *Bibliotheca universale sacro-profana*, designed to explain an immense number of words and to cover a wide range of other subjects besides history, biography, and mythology, was undertaken by a Venetian friar, Marco Vincenzo Coronelli. Of the 40 to 45 volumes projected, only seven were issued (1701–06), comprising A, B, and part of C. The book is confused in plan and material, but is notable as the precursor of the great modern general encyclopædias. In England the dictionary method was followed by John Harris (c.1667–1719), who compiled a *Lexicon Technicum; or an Universal English Dictionary of Arts and Sciences, explaining not only the Terms of Art, but the Arts themselves*, published in one volume (1704), and in a second edition of two volumes (1708–10). A supplement "by a society of gentlemen" appeared in 1744. It comprises technical history, geography, and astronomy; definitions of the terms of logic, metaphysics, ethics, grammar, and rhetoric; mathematics, astronomy, botany, etc. The text is illustrated with diagrams and figures. It was long in popular use. In Germany an excellent *Lexicon universale* (2 vols., 1677; with supplement, 2 vols., 1683) was compiled by J. J. Hoffmann. Notable also are the *Reales Staats-Zeitung und Conversations-Lexicon* (1704) and its supplement, *Curieuses und reales Natur-, Kunst-, Berg-, Gewerb-, und Handlungs-Lexicon* (1712), edited by Johann Hübner. They were the products of many hands and together furnish the first example of that systematic collaboration of scholars which characterizes the modern encyclopædia. A still more comprehensive work on this plan is the *Grosses vollständiges Universal-Lexicon aller Wissenschaften und Künste*, edited by Von Ludewig, Frankenstein, Longolius, and others, published 1732–54, in 68 volumes (four supplementary), especially valuable for its It is ordinarily known as / from its publisher, Johannes Heinrich Zedler, of Leipzig. An English work intrinsically much more important than that of Harris, mentioned above, is Ephraim Chambers's (died 1740) *Cyclopædia; or, an Universal Dictionary of Arts and Sciences, Containing an Explanation of the Terms and an Account of the Things signified thereby in the several Arts . . . and . . . Sciences. . . . Compiled from the Best Authors, etc.*, in two volumes (1728); second (1738) and third (1739) editions during the author's life. It is more comprehensive than Harris's *Lexicon* (though it omits history, biography, and various other subjects) and is of a more scholarly character. The systematic use of cross references, in order to enable the reader to obtain a connected view of general subjects, is especially noteworthy. A supplement, in two

volumes, published in 1753, was based largely upon materials collected by Chambers during the last years of his life. He may be regarded as the father of English encyclopædic lexicography, and he also exerted a wide influence upon continental literature in this department. The translation of his work issued at Venice (1748-49), in nine volumes, was the first completed Italian encyclopædia, while a French translation by John Mills and Gottfried Sellius was the foundation of the famous *Encyclopédie ou dictionnaire raisonné des sciences, des arts et des métiers*, commonly called, *par éminence*, "the Encyclopædia." The task of revising Mills's translation was intrusted by the publishers to Diderot, in whose hands it developed into the production of this original and far more ambitious work. With him were associated a large number of the most distinguished scholars of the age, including D'Alembert (who undertook to edit the mathematical articles and wrote the justly celebrated preface), Rousseau, Daubenton, Mallet, La Chapelle, D'Argenville, Louis, and Blondel. The greater part of the labor, however, fell upon Diderot himself, who was especially charged with the articles relating to the arts and trades as well as those in history and ancient philosophy, and, in addition, undertook the general revision and coördination of the materials contributed by the others. To him accordingly the credit for the result . . . belongs. In form the book is essentially an encyclopædic dictionary, containing both the common words of the language (substantives, verbs, adjectives, etc.) and proper names, accompanied by lexical descriptions and definitions, and also, in most cases, by more or less extended encyclopædic comments. It was designed "as an encyclopædia, to exhibit as far as is possible the order and system of human knowledge, and as a *dictionnaire raisonné* of the sciences, arts, and trades, to contain the fundamental principles and the most essential details of every science and every art, whether liberal or mechanical" (preface). In addition, it was made the vehicle of definite philosophical views, generally radical and in part materialistic, which brought upon it the condemnation of the orthodox and upon its editor much persecution. (See DIDEROT.) This characteristic has given it an important place in the history of modern thought. In this history those who were connected with it or accepted its views are called distinctively "the Encyclopædists." It was published (1751-72) in 28 volumes, including 11 of plates. Five supplementary volumes, with over 200 plates, appeared (1776-77), and an analytical table of contents in two volumes (1780), increasing the total number to 35. Many editions followed, and it was variously modified and supplemented.

In 1781 Charles Joseph Panckoucke (1736-98) published the plan of an *Encyclopédie méthodique et par ordre des matières*, which consisted in breaking up the material of Diderot's work into a series of independent dictionaries of particular subjects, to be compiled by special editors. This scheme, very much enlarged in scope, was carried out (after Panckoucke's death by his son-in-law, Henri Agasse, and Madame Agasse) in a series of 167 volumes, with 51 parts, containing over 6000 plates, completed in 1832. Of these volumes, 7 form a dictionary of zoology, 13 one of medicine, etc. The seed sown by Chambers was

also fruitful in England. His work was re-edited by Abraham Rees (1743-1825) in 1778, and again, with the incorporation of much new matter, in 1781-86, and was finally enlarged by him into the valuable *New Encyclopædia; or, Universal Dictionary of Arts and Sciences*, including biography, geography, history, etc., in 45 volumes (including 6 of plates, published in 1802-20).

As was remarked above, the tendency towards the dictionary type has been accompanied by a tendency towards the opposite (monographic) type. An illustration of the latter is the *Universal Dictionary of Arts and Sciences* (2 vols., London, 1745) of Dennis de Coetlogon, comprising 161 special treatises, arranged alphabetically by their subjects. A more important example is the *Encyclopædia Britannica*, first published in numbers in 1768 and completed (in 3 vols.) in 1771. It was planned by William Smellie (1740-95), a printer, who wrote the principal articles, and an engraver, Andrew Bell. It contained, like Coetlogon's work, distinct treatises and long articles, but also comprised definitions of technical and other terms, in alphabetical order. These general characteristics have been retained by each of the successive editions. Of these, the second was published in 1777-84, and the eleventh (29 vols.) in 1910-12. The so-called *Cabinet Cyclopædia* (133 vols., 1829-49), edited by Dionysius Lardner, is merely an aggregate of essentially independent special works, historical, scientific, etc. An extreme application of the true monographic method is the unfinished *Allgemeine Encyclopädie der Wissenschaften und Künste, in alphabetischer Folge*, edited by J. S. Ersch and J. G. Gruber, which contains articles several hundred, and even thousand, pages in length. It was begun in 1818, and, up to 1914, 168 volumes had been issued.

Since the beginning of the nineteenth century, to which we are brought by this historical review, little change has taken place in the theory of . . . making. The methods by that time established have been variously modified and combined, but not essentially altered. Progress has been made chiefly in the adaptation of methods and materials to practical needs, in the subdivision of the work of compilation and of editorial supervision among specialists, and in the consequent increase of accuracy in detail. There has, however, been a notable growth of the encyclopædic dictionary and of the special encyclopædia. The consideration of the former belongs strictly in the history of lexicography (see DICTIONARY); but several works of this kind fill in large measure the place of the encyclopædia and may be ranked as such. In character such a lexicon (which, as has been shown above, is no new invention) is an approximation of the true dictionary, or wordbook, to the encyclopædia, just as the modern encyclopædia is an approximation of the ancient encyclopædia to the dictionary. These two lines of development have actually met in the *Grand dictionnaire universel du XIX^{ème} siècle* (1865-78) of Pierre Larousse in 16 volumes (2 supplementary vols. were added later), and a *Nouveau Larousse Illustré*, 8 vols. (Paris, 1898-1904; supplement, 1907). This is a comprehensive dictionary (etymological and defining) of the French language and at the same time includes proper names and a vast amount of encyclopædic information. Although marred

by many imperfections, it is an exceedingly useful book. Its method has been followed in several other smaller dictionaries, but it cannot yet be said to be approved by lexicographers. Such a complete combination of the two classes of material is regarded, properly, as mechanical and, for other reasons, theoretically objectionable, however useful it may be. It is commonly held, in brief, that the encyclopædia, in encroaching upon the dictionary, should stop at the point where the true work of the latter begins, viz., the systematic collecting of the common words of the language and detailed statement of linguistic usage and history; while the dictionary, in invading the encyclopædic field, should exclude proper names and include only the technical information which is connected with its definitions, strictly so called. This limitation is observed in the dictionaries of which *The Century Dictionary: An Encyclopædic Lexicon* (6 vols., 1889-91; rev. ed., 12 vols., 1911), edited by W. D. Whitney, is the most notable example. The growth of the special encyclopædia has kept pace with the advance of knowledge and of industry. History, the various branches of science and technology, biography, theology, commerce, politics, law, the fine arts, etc., are all admirably represented in special works of this kind. Among the most important are the encyclopædias of biography. Some excellent examples of this class date from the seventeenth and eighteenth centuries; but those produced in the nineteenth century are much more numerous and, in several cases, far more comprehensive. The most notable of these later biographical works are the *Biographie universelle ancienne et moderne* (85 vols., 1811-62, including supplement; 2d ed., 45 vols., 1842-65) of Joseph and Louis Gabriel Michaud; the *Nouvelle biographie générale, depuis les temps les plus reculés jusqu'à nos jours* (46 vols., 1852-66), edited by Hoefer; and the *Dictionary of National Biography* (86 vols.; 1st supplement, 3 vols., 1885-1901; 2d supplement, 3 vols., 1901-11), edited by Leslie Stephen and Sidney Lee.

Some of the more noteworthy general encyclopædias, published during the nineteenth and early twentieth centuries, not mentioned above, are the following: In ENGLISH: the *Edinburgh Encyclopædia* (18 vols., 1808-30), edited by Sir David Brewster; the *Encyclopædia Metropolitana* (30 vols., 1818-45), edited by Edward Smedley, Hugh J. Rose, and Henry J. Rose—only in part alphabetically arranged; the *Penny Cyclopædia* (29 vols., 1833-46), edited by Charles Knight for the Society for the Diffusion of Useful Knowledge; the *English Cyclopædia* (27 vols., 4 supplementary, 1854-73), also edited by Knight; the *Encyclopædia* (10 vols., 1860-68), edited by Andrew Findlater, the new edition edited by David Patrick; *Encyclopædia Londinensis* (24 vols., 1810-29); *Encyclopædia Americana* (14 vols., 1839-47), edited by Francis Lieber; *The American Encyclopædia* (16 vols., 1858-63; new ed., 1893-97), edited by George Ripley and Charles A. Dana; *Johnson's New Universal Cyclopædia* (1874-78; revised, as *The Universal Cyclopædia*, in 12 vols., 1900), the latest edition edited by Charles Kendall Adams; *Blackie's Modern Cyclopædia of Universal Information* (9 vols., 1890), edited by Charles

Annandale; *A Dictionary of Science, Literature, and Art* (3 vols., 1872; new ed. of an earlier work by Brande), by W. T. Brande and G. W. Cox; *The Cambridge Encyclopædia: A Compendium of History, Religion, Chronology, Arts, Sciences, and General Information* (1899-; published monthly); *Nelson's Encyclopædia* (12 vols., 1906-07); *The Americana* (22 vols., 1912); *The International Cyclopædia* (New York, 1884, new eds., 1891, 1894, 1898), now discontinued and superseded by the present work, *THE NEW INTERNATIONAL ENCYCLOPÆDIA*, in 20 volumes (1902; 2d ed., 24 vols., 1914-).

In GERMAN: *Brockhaus's Konversations-Lexikon* (1796-1808; subsequently often revised and greatly enlarged; 14th ed., 17 vols., 1 supplementary, 1892-97; again revised, 1901-04), one of the most serviceable and scholarly encyclopædias in any language, especially noteworthy in method as a happy mean between excessive subdivision of material and the monographic type (see above); *Pierer's Universal-Lexikon, oder encyclopædisches Wörterbuch der Wissenschaften, Künste und Gewerbe* (26 vols., 1824-36; 7th ed., 12 vols., 1888-93); *Meyer's Neues Konversations-Lexikon* (37 vols., 1839-52; 6th ed., 1902-08; 3 supplementary vols., 1909-11), a work of much the same quality as that of Brockhaus; *Allgemeine Real-Encyclopädie oder Konversations-Lexikon für das katholische Deutschland* (12 vols., 1846-51; 4th ed., 13 vols., 1880-90); *Wetzer and Welte's Kirchen-Lexicon* (13 vols., 1847-60; 2d ed., 1882-1901).

In FRENCH: *Encyclopédie des gens du monde; répertoire universel des sciences, des lettres et des arts, etc.* (22 vols., 1833-44); *Dictionnaire de la conversation et de la lecture* (52 vols., 1832-39; supplement, 16 vols., 1844-51; 2d ed., 16 vols., 1851-58; 3 supplementary vols., 1865-82); *Encyclopédie abrégée des sciences, des lettres, des arts, de l'industrie, de l'agriculture et du commerce* (26 vols., 1823-32; new ed., 27 vols., with 12 supplementary vols. and an atlas, 2 vols., 1847-62), edited by Courtin; *Encyclopédie du XIX^{ème} siècle répertoire universel des lettres, des sciences et des arts, avec la biographie de tous les hommes célèbres* (28 vols., 1837-59; 2d ed., 1858-64; continued as *Annuaire encyclopédique*), edited by Ange de Saint-Priest; *Dictionnaire encyclopédique universel, illustré de 20,000 figures* (1895-), conducted by E. Flammarion; *La grande encyclopédie: inventaire raisonné des sciences, des lettres et des arts, etc.* (31 vols., 1886-1902).

In OTHER LANGUAGES: *Nuovo Enciclopedia popolare* (14 vols., Turin, 1841-51); *Dizionario universale di scienze, lettere ed arti* (Milan, 1874), by Lessona and Valle; *Enciclopedia popolare italiana* (ib., 1872), edited by Giovanni Berri; *Enciclopedia universale o repertorio didascalico* (5 vols., Prato, 1868); *Nuova enciclopedia italiana, etc.* (25 vols., Turin, 1875-88), by G. Boccardo; *Enciclopedia moderna* (34 vols., with an atlas, Madrid, 1848-51), by Mellando; *Diccionario enciclopédico Hispano-Americano de literatura, ciencias y artes* (25 vols., Barcelona, 1857-60), by Montaner y Simon; *Diccionario universal de la lengua castellana, ciencias y artes* (3d ed., 15 vols., 2 supplements, with "album," Madrid, 1879-81), based on the plan of Nicolás María Serrano; *Enciclopedia Seguí* (Barcelona, 1907-).

6 vols. to 1914); *Diccionario popular historico geographico, mythologico, etc.* (16 vols., Lisbon, 1876-90), by Chaga; *Diccionario universal portuguez illustrado*, by Zeforina; *Salmonsens's store illustrerede Konversations-leksikon* (19 vols., Copenhagen, 1891-1911); *Geillustreerde encyclopedie: woordenboek voor wetenschap en kunst* (2d ed., 16 vols., Rotterdam, 1884-88); *Nordisk Familjebok* (Stockholm, 1904- , 15 vols. to 1911); *Entsiklopedichesky Slovar* (St. Petersburg, 41 vols., 1890-1904; 2 vols., supplement, 1905-06); *Bolshaya entsiklopedia* (ib., 1901- ; 8 vols. issued); *Encyclopédia Powszechna, etc.* (16 vols., Warsaw, 1898-1904), by S. Orgelbrand.

ENCYCLOPÉDIE, ǎn'sé'klô'pâ'dé', ou DICTIONNAIRE RAISONNÉ DES SCIENCES, DES ARTS ET DES MÉTIERS (Fr. *Encyclopædia*, or Classified Dictionary of Sciences, Arts, and Trades). A celebrated French work, published by Diderot and D'Alembert at Paris in 1751-72, which in philosophy, religion, and politics voiced the prevailing tendencies of the time. Among the collaborators were many of the great writers of the day—Rousseau, Grimm, Montesquieu, and Voltaire, in addition to the principal editors. The work aroused violent opposition and encountered many obstacles, its publication being repeatedly suspended by the government, but was carried to completion largely through the secret aid of Madame de Pompadour. It gave rise to the term "Encyclopédistes," by which those who accepted its philosophy were called. See *ENCYCLOPÆDIA*.

END. See TELELOGY.

ENDE, ɛn'de, **HERMANN** (1830-1907). A German architect. He was born at Landsberg, attended the Academy of Architecture at Berlin, and afterward made a tour of Europe. He has exercised a considerable influence upon the recent development of architecture in Berlin. The numerous buildings constructed by him (partly in association with Wilhelm Böckmann) include the Red Palace, the buildings in the Zoölogical Garden, Royal York Lodge, Ethnological Museum, and the Bank of Commerce and Industry. The Japanese government intrusted him in 1866 with contracts for the designs of several new public buildings at Tokyo and elsewhere. He was made a member of the Berlin Academy of Arts and honorary member of those of Vienna and St. Petersburg. He was from 1885 to 1901 head professor in the High School for Technical Arts at Berlin.

ENDEAVOR, THE. The famous ship in which Lieutenant (afterward Captain) Cook made his voyage of exploration and discovery (1768-71) in the Southern Pacific. It was fitted out by the Royal Society of England for the express purpose of observing the transit of Venus. See *COOK*. CAPT. JAMES.

ENDECOTT, JOHN (c.1588-1665). A Colonial governor of Massachusetts, born in Dorchester, England. He was one of the six "joint adventurers" of Dorchester who, in March, 1628, obtained a patent of the Massachusetts Bay Territory, and in the same year led the company of about 100 which, early in September, settled at Naumkeag (later Salem). He acted for a time as Governor, but in June, 1630, was superseded by Winthrop. Endecott then became a member of Governor Winthrop's Council of Assistants. In August, 1636, Endecott led an expedition against the Pequots on Block Island, but accomplished little. He was Deputy

Governor of the Colony in 1641-44; served as Governor in 1644-45; became sergeant major general of Massachusetts in 1645, and from 1649 until his death, with the exception of 1650 and 1654, when he was Deputy Governor, was Governor of the Colony. In 1658 he was elected President of the United Colonies of New England. During his term as Governor he served the interests of the Colony with great ability and energy. He was bigoted, and especially harsh towards the Quakers; but he was a true friend to Roger Williams in his troubles. Consult C. M. Endicott, *Memoir of John Endecott* (Salem, 1847), privately printed, but reproduced in part in vol. i of *The New England Historical and Genealogical Register* (Boston, 1847), and a "Memorial of Governor John Endecott," by Salisbury, in *Antiquarian Papers* (Worcester, 1879).

ENDEMANN, ɛn'de-màn, **WILHELM** (1825-99). A German jurist, born at Marburg, Hesse, and educated at Heidelberg. He was professor of law at Jena from 1862 to 1867, assuming in the latter year the same chair at Bonn. From 1871 to 1873 he was a member of the Reichstag. He became one of the greatest authorities on the commercial law of Germany. His works on jurisprudence include: *Der Entwurf eines deutschen Handelsgesetzbuchs* (1858); *Das deutsche Handelsrecht* (4th ed., 1887); *Die Entwicklung des Beweisverfahrens im deutschen Civilprozess* (1895).

ENDEMIC (from Gk. ἐνδημος, *endēmos*, native, from ἐν, *en*, in + δῆμος, *dēmos*, people). A term applied to diseases which affect numbers of persons simultaneously, but so as to show a connection with localities as well as with their inhabitants. Endemic diseases are usually spoken of as contrasted with epidemic (q.v.) and sporadic (q.v.), the first term indicating that a disease infests habitually the population within certain geographical limits, and also that it is transferred or communicated beyond those limits only to a limited degree; while, on the other hand, a disease is termed epidemic if it is transmitted without reference to locality, and sporadic if it occurs in isolated instances only. The theory, accordingly, of endemic diseases is that they are in some way or other connected with the soil, the climate, the water supply, the customs of the people, and the microbes natural to the locality. The most marked types of an endemic disease are intermittent malarial fever in many parts of the United States or yellow fever in Brazilian coast districts.

ENDEMISM (from Gk. ἐνδημος, *endēmos*, native). In botany, the restriction in area of geographical distribution, commonly resulting from long-continued isolation; the opposite of cosmopolitanism. Somewhat famous cases of endemism are the big trees, or sequoias, of California, which, like most endemic forms, represent the scattered remnants of a former widespread race. Vicarious endemism is the condition in which the dying race, especially if occurring in several disconnected areas, splits up into various species. Relict endemism, on the other hand, is the connection in which a species suffers gradual reduction in area without essential change in specific characters. Still another type of endemism is where new species have arisen by mutation in areas where their migration was restricted. Without knowing the history of the species, this cannot be dis-

tinguished from vicarious endemism. The saxifrages, gentians, and evening primroses, with their local and isolated forms, represent either vicarious endemism or mutation endemism. Relict endemism is well illustrated by the two living species of sequoia, each the last representative of distinct and once world-wide species, and also by the once widely distributed bald cypress. Endemism depends, not upon the size of a district, but upon its barriers—e.g., Germany has no endemic species, while the Alps have 200. Within the United States no region is so remarkable for its abundance of endemic species as California. It has, in addition to the sequoias already mentioned, two cypresses, five pines, and several other conifers found nowhere else in the world. Speaking generally, the longer the isolation, the greater the endemism of a region. See DISTRIBUTION OF PLANTS.

ENDER, ɛn'dēr. An Austrian family of painters, all born in Vienna.—**JOHANN** (1793–1854), historical and portrait painter, was a pupil of Maurer and others at the Vienna Academy, where he obtained the great gold medal. He made an early success in painting portraits, almost exclusively in the circles of the aristocracy, and in 1818–19 traveled in Hungary, Széchenyi in Italy, Greece, and Turkey. He later lived in Rome and Paris, returning finally (in 1826) to Vienna, where he became celebrated as a painter of miniature portraits, in the manner of Isabey, besides producing a considerable number of historical paintings. From 1829 to 1850 he was professor at the Academy. A "Madonna with the Christ-Child Slumbering at her Feet" is in the Vienna Art Museum; but his best work is a fresco painting of the "Crucifixion" (1850–52), in one of the chapels in the cathedral at Vienna.—**THOMAS** (1793–1875), twin brother of Johann, was a pupil of Mössmer and Steinfeld at the Vienna Academy. He formed his style chiefly after Ruysdael and Claude Lorrain and painted hundreds of so-called "picturesque" landscapes, which are monotonous, but not without charm, and sometimes are effective in color. In 1817 he accompanied the Austrian expedition to Brazil, whence he brought back over 900 drawings and water colors of natural scenery and buildings. In 1819 he went with Prince Metternich to Italy, remained four years in Rome, also visited Palestine and Greece, and in 1826 Paris. He was professor at the Vienna Academy from 1836 to 1852. Of his numerous Austrian mountain landscapes, a "View of the Grossglockner," "The High Göll near Berchtesgaden," "Castle Tyrol," and "Val de Non in South Tyrol" are in the Museum of Vienna.—**EDUARD** (1824–), son and pupil of Johann, devoted himself especially to historical genre. All his pictures are pleasing in composition, bright in color, but his canvases illustrative of homely life really display greater merits. To the former class belong: "Tasso at the Court of Ferrara"; "Francis I in the Studio of Cellini"; "Shakespeare Reading Macbeth before the Court of Elizabeth"; "Young Mozart Presented to Joseph II"; and of the genre scenes pure and simple, "La Corbeille de Mariage" (1850) and "A Game of Chess" (1857) are among the best.

ENDERBY LAND. A region in the Antarctic Ocean, in lat. 66° S., long. 47° 20' to 49° E. (Map: Antarctic Regions, G 3). It was discovered by Captain Biscoe, an English

navigator in the employ of Messrs. Enderby, of London, in 1831, in whose honor he named the land. Innumerable icebergs and impenetrable field ice prevented Biscoe from approaching nearer than about 30 miles. A probable extension (Kemp Land) of Enderby Land to the eastward was discovered in 1833. These lands are doubtless the northern edge of the ice-clad continent of Antarctica. See ANTARCTIC REGION. Consult also Mill, *Siege of the South Pole* (New York, 1905).

ENDERMIC (from Gk. *ἐν*, *en*, in + *δέρμα*, *derma*, skin) and **HYPODERMIC** (from Gk. *ὑπό*, *hypo*, under + *δέρμα*, *derma*, skin). Terms used to designate certain methods of making the skin an avenue for the reception of medicines. The endermic method consists in raising a blister by the ordinary process, opening it by a small puncture, which must not be at the lowest part of the bladder, gently pressing out the fluid contents, and then injecting a medicinal solution, by means of a small syringe, through the puncture into the emptied sac; or, if the medicine is in the form of powder, it may be scattered over the raw surface. The endermic method is now superseded by the hypodermic method, in which medicines are introduced into the subcutaneous cellular tissue by means of a very finely pointed syringe. For the invention of this process the science of medicine is indebted to Dr. Alexander Wood, of Edinburgh. See HYPODERMIC MEDICATION.

EN'DICOTT, MORDECAI THOMAS (1844–). An American naval officer, born at May's Landing, N. J. He was educated at the Rensselaer Polytechnic Institute (C.E., 1868). In 1874 he was appointed civil engineer in the United States navy. He served as consulting engineer in various navy yards and in the Department at Washington, became a member of the Nicaragua Canal Commission in 1895, of the United States Armory Factory Board in 1897, and of the Isthmian Canal Commission in 1905. He was promoted commodore in 1898 (later rear admiral), and, being appointed chief of the Bureau of Yards and Docks, was reappointed in 1902 and 1906. Although retired in the latter year, he remained in active service until 1909. He was president of the American Society of Civil Engineers in 1911.

ENDICOTT, WILLIAM CROWNINSHIELD (1826–1900). An American politician and jurist, a descendant of John Endecott (q.v.). He was born in Salem, Mass., graduated at Harvard in 1847, was admitted to the bar in 1850, and from 1873 to 1882 was a justice of the State Supreme Court. He was a Whig until the dismemberment of that party, when he became a Democrat. In 1884 he was an unsuccessful candidate for Governor and from 1885 to 1889 was Secretary of War in President Cleveland's cabinet. Joseph Chamberlain, the English politician, married Endicott's daughter.

EN'DIVE (Fr. *endive*, ML. *intiba*, Lat. *intibus*, *intibum*, endive), *Cichorium endivia*. An annual or biennial plant. of the same genus with chicory (q.v.), considered to be a native of the East. It has long been in cultivation as a garden vegetable in Europe and America, its blanched root leaves being much used as a salad and in soups. It is grown like lettuce, on any good garden soil, and is blanched by lightly tying the outer leaves together. In general, those varieties that are most curled, and that naturally begin to blanch before being tied

are in the United States considered to be of a superior quality to the broad-leaved and more persistently green sorts. Many varieties are grown in Europe; among the most popular are the moss-curved, Rouen, and broad-leaved. For illustration, see Plate of SALAD PLANTS.

ENDLESS SCREW. A popular name, and one which is not scientifically correct, often given to a screw or helix upon a cylindrical surface which is restrained from motion endwise as it turns, and which meshes or engages with helical teeth on the circumference of a toothed wheel. When the screw (often called a worm in this usage) turns, the wheel is slowly turned. The mechanical combination gives a great reduction of velocity ratio, since one revolution of the screw turns the wheel through the angular space subtended by one tooth. Hence it gives great power, less the losses by friction. It is much used in elevators and in electric hoisting; in the transmission mechanism of electric and other motor vehicles; in fine adjustments for astronomical and other instruments of precision. The screw is only endless because it does not advance or retreat out of the nut or female screw. The latter advances, and not the screw. The worm and wheel are usually on axes at right angles to each other, and the worm in the plane of the wheel. This is not necessary, however. In the Hindley worm the helix is not on a cylinder, but on a hyperboloidal surface, so that more than one tooth of the wheel engages with the helical driving elements. See GEARING.

ENDLICHER, ěnt'lik-ěr, STEPHAN LADISLAUS (1804-49). A distinguished Austrian botanist and Sinologist, born at Pressburg, Hungary. He was educated in his native town and at the universities of Pest and Vienna, and entered the church, which career, however, he abandoned after a few years. In 1827 he began his botanical and linguistic studies, and the following year he was placed in charge of the manuscript department of the Imperial Library at Vienna. In 1836 he was appointed curator of the botanical department of the Royal Natural History Museum at Vienna, and in 1840 he became professor of botany in the university and director of the Botanic Garden. Together with Ettinghausen and others, he took a prominent part in the establishment of the Vienna Academy of Sciences. Endlicher's publications were principally upon systematic botany, upon the study of which subject he exerted great influence. Some of his works are: *Flora Posoniensis* (1830); *Grundzüge einer neuen Theorie der Pflanzenzeugung* (1838); *Grundzüge der Botanik*, with Unger as co-author (1843); *Synopsis Coniferarum* (1847). His most important contribution to botany was his elaboration of the natural system of classification of plants, announced in *Genera Plantarum Secundum Ordines Naturales Disposita* (1836-50), and in *Enchiridion Botanicum Exhibens Classes et Ordines Plantarum* (1841). In connection with Hügel and Nees von Esenbeck, Endlicher edited several important botanical works dealing with descriptions of foreign plants preserved in the Vienna Botanical Garden. Endlicher's study of classical and Oriental history and literature resulted in the publication of important contributions to the knowledge of these subjects, among which may be cited: *Anfangsgründe der chinesischen Grammatik* (1845); *Verzeichnis der chinesischen und japanesischen Münzen des*

kaiserlichen Münz- und Antikenkabinets (1837); *Analecta Grammatica*, with Eichenfeld as co-author (1837).

ENDOCARDITIS (Neo-Lat., from Gk. ěndon, *endon*, within + *kapěla*, *kardia*, heart). Inflammation of the endocardium, or serous membrane lining the internal surface of the heart. It may be either acute or chronic, simple or malignant. Rheumatism, tonsillitis, and gout are the most frequent causes of the simple acute form, which generally ends in recovery. Malignant (known also as ulcerative, diphtheritic, or septic) endocarditis is, as these terms imply, due to septic infection, most frequently in connection with scarlet fever, and very fatal. It is characterized by high fever, rigors, and extreme prostration with delirium, convulsions, and death. In the simple forms of endocarditis there is an inflammation with exudation of plastic lymph upon the diseased membrane, particularly that covering the cardiac valves, which become distorted and thickened, giving rise to the so-called cardiac murmurs. This fibrinous deposit may accumulate in masses called "vegetations," which project into the heart cavities. Pieces of these are sometimes dislodged by the blood and carried to the brain or other parts of the body, giving rise to embolism (q.v.). Again, these thickened areas may become atheromatous or may ulcerate. Treatment of the accompanying gouty or rheumatic conditions, and certain medicines, such as digitalis, aconite, morphia, may prove curative, or at least may tide the patient over the acute stage. Few patients recover without resulting valvular trouble. See HEART, DISEASES OF THE.

ENDOCERAS, ěn-dōs'ě-ras. An important genus of fossil cephalopods, found abundantly in many species in the Ordovician rocks of Russia, Scandinavia, and the United States. The conch is straight, long, and slender, annulated or smooth. The septa are extended into siphuncular funnels, that reach from the septum of origination to the one next posterior to this. The siphuncle is wide and filled with organic calcareous deposits in the form of cones (endocones). These solid siphuncles of *Endoceras* fill the Beekmantown and Trenton beds. The order of Nautiloidea reaches its largest size in this genus, specimens of which have been found in the Trenton rocks of New York with a length of over 10 feet. The best-known species is *Endoceras proteiforme* from the Trenton limestone. See CEPHALOPODA.

ENDOCHROME (from Gk. ěndon, *endon*, within + *chrōma*, *chrōma*, color). The characteristic pigment mixture of diatoms (see DIATOMACEÆ). In a diatom two or more brownish-yellow chromoplasts (color bodies) occur, often called endochrome plates. The endochrome seems to be a mixture of a green constituent (possibly chlorophyll) and a golden-brown constituent (diatomin).

ENDODERM, ENTODERM (from Gk. ěndon, *endon*, within + *děrma*, *derma*, skin), or HYPOBLAST. The inner layer of the embryo. See EMBRYOLOGY.

ENDODERMIS (Neo-Lat., from Gk. ěndon, *endon*, within + *děrma*, *derma*, skin). In plants, a layer of cortical cells which surrounds the vascular region (stele) (q.v.) as a sheath; also called the bundle sheath. In some cases there is but a single bundle sheath, which surrounds a solitary general vascular region; in other cases there may be several vascular regions in a stem, each surrounded by its own endodermis.

The endodermis is quite variable in its definiteness. Its cells may be indistinguishable from other cortical cells, in which case the name is merely one of position. As ordinarily used, however, the name indicates a layer of cells very different in appearance from the ordinary cortical cells. The corresponding external layer of the stele, against which the endodermis abuts, is called the pericycle (q.v.). See MORPHOLOGY OF PLANTS.

ENDO'GAMY. A term correlative with exogamy (q.v.) and meaning enforced marriage within a social or political group. It has been applied to the custom of marrying within, rather than without, the tribe, but in this sense the term is of no special value, since there is naturally among most peoples a preponderance of unions between members of the same tribe. Accordingly endogamy is now generally restricted to corresponding regulations applying to tribal subdivisions. One of the best-known illustrations is furnished by the Hindu caste system, while the tendency in civilized society against mating of members of different social strata may be cited as a modern analogue. No one now holds that endogamy represents a stage in the evolution of marriage through which all tribes once passed, and strictly endogamous communities are not nearly so common as those practicing exogamy. Among those of which we have the clearest accounts may be cited the Todas of India, who are subdivided into endogamous moieties, which in turn are subdivided into exogamous gentes; that is to say, an individual must marry within his moiety but outside his gens. It may be noted that endogamous rule applies only to what might be called legal marriage and does not exclude concubinage between members of complementary moieties. Endogamy may arise from different psychological motives. Thus, among the Bella Coola it has nothing to do with pride of blood, but represents the desire to keep certain highly prized traditions the exclusive property of the village community. Consult Rivers, *The Todas* (London, 1906), and Goldenweiser, "Totemism, an Analytical Study," in *Journal of American Folk Lore* (1910).

ENDOGENS (Neo-Lat. *endogenus*, from Gk. *ἔνδον*, *endon*, within + *-γενής*, *-genēs*, producing, from *-γίγνεσθαι*, *gignesthai*, to become). An obsolete term formerly applied to monocotyledons (q.v.).

ENDOMETRITIS. See UTERUS, DISEASES OF THE.

ENDOPARASITE. A parasite which lives within the body of its host. Among plants the rusts and smuts are common examples of endoparasites, as during the months of vegetative growth the fungi are within the stems of the grain, appearing upon the surface only when their spores are produced. See PARASITE; PLANT PATHOLOGY.

ENDOPHYTE, or ENTOPHYTE (from Gk. *ἔνδον*, *endon*, or *ἐντός*, *entos*, within + *φυτόν*, *phyton*, plant, from *φύειν*, *phyein*, to produce). A plant which grows inside another plant. See SYMBIOSIS.

EN'DOR. A place near Mount Gilboa, in Palestine, where King Saul visited a witch who, by the art of necromancy, raised for him from the dead the prophet Samuel, according to 1 Sam. xxviii. 3-25. In the fourth century A.D. a large town 4 Roman miles south of Tabor bore the name Endor, and a small village 7

or 8 miles from the slopes of Gilboa still possesses it as Endur.

ENDORSE' (from OF. *endorser*, ML. *indorsare*, to indorse, from Lat. *in*, in + *doisum*, back). In heraldry (q.v.), a subsidiary, equal to one-eighth or one-fourth part of a pale.

ENDORSEMENT. See INDORSEMENT.

EN'DOSPERM (from Gk. *ἐνδον*, *endon*, within + *σπέρμα*, *sperma*, seed, from *σπείρειν*, *speirein*, to sow). The nutritive tissue developed within the embryo sac of the seed and used by the embryo. An obsolete term for it is albumen. See SEED.

EN'DOTHE'Cium (Neo-Lat., from Gk. *ἔνδον*, *endon*, within + *θήκη*, *thēkē*, case). A term which has two applications among plants. The endothecium of autheirs is a layer of cells immediately beneath the epidermis, which is usually more or less modified in relation to dehiscence. It received its name from the fact that it is the inner one of the two layers of cells that constitute the wall of the mature anther. The endothecium of Bryophytes is one of the two genetic regions of the spore case, the outer being called amphithecium. The groups of Bryophytes differ as to the products of these two genetic regions.

EN'DOTHE'LIO'MA. See TUMOR.

EN'DOTHE'Lium (Neo-Lat., from Gk. *ἔνδον*, *endon*, within + *θήλη*, *thēlē*, nipple). A tissue which serves as the lining of certain closed cavities and tubes of the body. It covers the serous surfaces of the pleura, the pericardium, the peritoneum, and the synovial membranes of the joints, and lines the entire vascular system, heart, arteries, veins, and capillaries, as well as the lymphatic vessels and spaces. Endothelium consists of a single layer of thin, delicate, platelike nucleated cells united with one another by a small amount of cement substance. The cells differ somewhat in shape and size. Thus, those lining the serous cavities are polyhedral scales resembling squamous epithelium. On the other hand, those lining the blood vessels are long and irregularly spindle-shaped. Recent histological classification places endothelium among the epithelial tissues. See EPITHELIUM.

ENDOTH'YRA (Neo-Lat. nom. pl., from Gk. *ἔνδον*, *endon*, within + *θύρα*, *thýra*, door). A genus of fossil Foraminifera, of interest because the minute shells of one of its species, *Endothyra baileyi*, form a large part of the light-gray oolitic limestone of Lower Carboniferous age, known as Bedford limestone. The shells occur by myriads in the limestone associated with fragments of other minute organisms and with oolitic grains of carbonate of lime. See FORAMINIFERA; CARBONIFEROUS SYSTEM.

EN'DOTROPH'IC. See MYCOORRHIZA.

ENDOWED SCHOOLS ACTS. Acts of Parliament made to prevent misapplication and abuse of the foundations for the support of secondary education in England. Consult Balfour, *The Educational Systems of Great Britain and Ireland* (Oxford, 1912). See NATIONAL EDUCATION, SYSTEMS OF; GREAT BRITAIN, Education.

EN'DROMIS (Lat., from Gk. *ἑνδρῶμις*; cf. *ἐν*, *en*, in, and *δρόμος*, *dromos*, a running, a race). A kind of boot worn by (ancient hunters and by Artemis, and then by runners (cf. the etymology above) and athletes in general. It was close-fitting and reached some distance above the ankle; the top turned over and hung down in a flap.

The boot was open in the front; on each side of the front were eyeholes, through which the laces were run. The Romans called the endomis of Diana a cothurnus. (See BUSKIN.) The Romans gave the name "endomis" also to a thick woolen rug worn after violent exercise, or used by the lower classes as protection against rain or cold. Such rugs came from Spain and from Tyre.

ENDYMION (Lat., from Gk. *Ἐνδυμιών*). According to the Elean story, the son of Aethlios or of Zeus and Calyce. He led the Ætolians to Elis and became King of that country. His grave was shown at Olympia. He was also said to have received from Zeus, at his own request, the gift of eternal sleep with perpetual youth. He was beloved by Selene (the moon), who bore him 50 daughters, i.e., the 50 months of the Olympian cycle. The love of Selene for Endymion, however, is more commonly connected with another form of the story, according to which Endymion was a youthful hunter on Mount Latmos, in Caria; in a cave in that mountain he sleeps forever, visited nightly by Selene, who has given him this sleep that she may kiss him unperceived. Other versions made this sleep a gift of Zeus, as reward for piety, or a punishment for his presumption, when, translated to the gods on Olympus, he had dared to fall in love with Hera. The sleeping Endymion visited by Selene is represented in ancient wall paintings and especially on Roman

Consult Robert, *Antike Sarkophag.* i. iii (Berlin, 1898); J. E. B. Mayor's note on Juvenal, x, 318 (London, 1888). The story of Endymion is the subject of a poem by Keats.

ENEMA (Neo-Lat., from Gk. *ἐνema*, injection, from *ἐν*, *en*, in + *ίεναι*, *hienai*, to send). A fluid substance conveyed into the bowel by injection through the anus. Enemata are used to cause an evacuation of the bowels, or for the introduction of food which cannot be administered by the stomach, or for the administration of medicine. For evacuation of the bowels, an enema of warm water, or soapsuds, or soapy water containing a few drops of turpentine, or olive oil, is used. For nourishment, raw eggs, beef juice, defibrinated blood, or peptonized milk may be introduced. In cases of convulsions, bromides or chloral may be given by the rectum. Enemata are also given to lower the body temperature, to restore the volume of blood which has been lost by severe hemorrhage, and to promote the action of the kidneys. A mixture of ether and olive oil introduced into the rectum is sometimes employed to induce general anæsthesia. In cases of fecal impaction or in some cases requiring nutrient enemata, instead of the ordinary Davidson's syringe or a fountain syringe alone, a long rubber tube must be inserted into the colon first and the syringe attached to this.

ENEMY (OF. *enemi*, *anemi*, Fr. *ennemi*, Portug. *inimigo*, enemy, from Lat. *inimicus*, foe, from *in-*, not + *amicus*, friend, from *amare*, to love). In international law, a nation at war with another, considered as a whole or an individual or body of men belonging to the hostile nation. An enemy, in the latter sense of the term, may or may not be a belligerent, but there can in international law be no enmity without the existence of a state of belligerency. Accordingly, no matter how strained the relations of two states may become, they do not

assume the position of enemies towards each other until a state of war arises between them. Nor does the active intervention of a third state or its active sympathy with one of two combatants, even though it be bound to the latter by an offensive and defensive alliance, make it the enemy of the other, until it, too, becomes a party to the war.

An enemy's status in international law depends on whether it is a combatant or a non-combatant. Against the former the whole force of the opposing belligerent state may and should be exerted, with a view to its destruction or subjugation. This is true of the government of the enemy, its civil as well as its military and naval representatives—of all, in fact, who, owing it allegiance, are directly or indirectly engaged in carrying on the war. It is probable, however, that at the present time judges and minor civil servants having no direct connection with the war, as well as diplomatic agents accredited to neutral powers, would be deemed to be non-combatants, though there are modern examples to the contrary.

Noncombatants—i.e., such of the subjects of the enemy state as have no connection with the war, but are engaged in peaceful pursuits—are, by modern usage, exempt from hostile attack. The old theory that, when a state of war existed, each and every subject of the one belligerent was at war with each and all of the subjects of the other, has been superseded in practice by more humane principles. Commercial relations between the subjects of the respective belligerents are, however, suspended, contracts between them are rendered null and void, and the courts of each are closed to the subjects of the other. See ALIEN.

Noncombatants residing in their own country are equally exempt from the worst horrors of war. Though they may suffer incidentally, as the result of the bombardment of fortified places and the destruction, as a matter of military policy, of crops and other property, they are not ordinarily liable to injury either in person or property by any hostile operations. If attacked or plundered by unauthorized acts of soldiers belonging to the enemy, the latter become liable to punishment by their own martial law for violation of the rules of civilized warfare.

The treatment which modern international law accords to combatants will be more appropriately considered in the article on WAR. It will suffice to say here that the mitigation of the horrors of war has not been confined to exempting the greater part of the enemy's population from the list of its victims, but has been extended to the actual conduct of warlike operations on land and sea. It is a marked tendency of modern warfare between civilized nations to confine all public acts of hostility to the actual combatants and to the field of battle.

In their dealings with uncivilized races, however, the Christian nations have not yet reached the same standard of humanity, but continue to confound combatants and noncombatants and to employ against both classes the stern and indiscriminate methods of warfare of a more barbarous age. See ALIEN; BELLIGERENT; WAR; and the authorities there referred to.

ENERGETICS (Gk. *ἐνεργητικός*, *energētikos*, active, from *ἐνεργειν*, *energein*, to be active, from *ἐν*, *en*, in + *εργον*, *ergon*, work). The

theory of energy; a theory which states the conditions and laws under which the phenomena of energy are manifested. Energy, pending a more technical definition, may be understood broadly to be a condition or attribute by virtue of which matter can effect changes in other matter.

The modern doctrine of energy, dating from 1840, takes the phenomena of physical science from the position of speculative reasoning or of disconnected and unrelated occurrences and unites them in one general scheme of exact quantitative relationship.

A force applied to a body so as to move it is said to do work, and the measure of the work is the component of the force in the direction of motion, multiplied by the distance through which its point of application moves, or, calling the work W , the force F , and the space s , $W = Fs$. We may interpret this relation from either point of view: if we recognize the force and the distance traversed, we derive the work from their product; if we appreciate the work in the first place, we recognize the force as the relation of the work to the space in which it was performed, since $F = \frac{W}{s}$.

Experiment shows that a constant force applied to a body free to move varies as the mass, m , of the body, and the rate of change, $\frac{v}{t}$, in its velocity, and by a suitable choice of units the relation may be stated $F = m \frac{v}{t}$, if v is the velocity produced in time t by the constant force F ; furthermore, the space s , traversed in time t , while its velocity is increasing from 0 to v , is $s = \frac{1}{2} \left(\frac{v}{t} \right) t^2$. Combining these two

equations we find $Fs = \frac{1}{2}mv^2$. That is, a body of mass m , free to move by the application of a force F , would acquire a velocity v , when it had been moved over a distance s , such that $Fs = \frac{1}{2}mv^2$. The expression Fs is the measure of the action viewed with regard to the agent, $\frac{1}{2}mv^2$ that with regard to the body; the former is called work, the latter energy. In this particular case, however, the only change that has been produced in the body is a change in its motion, but the body is now possessed of more ability to change other bodies than it possessed before, and in being brought back to its original state of rest or motion it is found to be able either to do mechanical work equal to Fs , or to confer on other bodies a motion such that the total value of $\frac{1}{2}mv^2$ for them is exactly equal to that for the given body. This is a simple form of conversion or transference of energy. Energy due to motion only is called *kinetic energy*. The same amount of work might have been done as before, resulting in a static condition of the body upon which work has been done, as, e.g., in compressing or stretching an elastic body; but the body would now be in condition to do work on its own account, i.e., it would possess energy, though not itself in motion. Here a strain has been produced by changing the position of some or all parts of the body. Similarly a body might have conferred upon it power to do work by changing it from one place to another, as when a body is lifted to a point above the earth. It should not be thought, however, that the change in position is the essential feature of the phenomenon; it is

the *visible* portion of it only. Undoubtedly the real seat of the energy is connected with the hidden mechanism which renders it necessary to use a force in order to secure the strain or change in position, e.g., the mechanism of gravitation. Energy due to strain or to position is called *static energy*, or *potential energy*. (The term "energy" is due to Thomas Young, "potential energy" to Rankine, "static energy" to Kelvin.) This affords a more precise definition of energy as the *capability to do work*, and the amount of energy which a body possesses is its *capacity for doing work*. Work, too, may now be regarded as a transference of energy from one body to another. Conceive of a body in a state of strain, as a bent spring, and possessing energy, in consequence of its strain, equal to the work done in bending it. If it is permitted to straighten itself out in part, thereby moving some other body, it does work on this body; and if the only effect is to give it a certain velocity, the kinetic energy the body acquires will exactly equal the work done by the spring. But the spring will now possess less energy, less capacity for doing work, by the amount it has done; the energy it loses equals that gained by the other. The total energy of the two, however, is the same as before. If the two bodies are viewed as comprising a system, the total energy of the system is not altered by any exchange of energy between its parts. We may extend this consideration indefinitely. Given a system of bodies arranged in a definite configuration and with certain stresses between them: if in obedience to these stresses a rearrangement of the bodies takes place, a change of configuration ensues, the energy of the parts may be altered, but the total is not changed. The energy is conserved, and such a system is called a conservative system. So far as known, all material systems are conservative. The energy of such a system is a quantity that can neither be increased nor diminished by any action between the bodies themselves, though the form of energy may be changed. If the total energy is to be increased, it can only be done by work expended upon the system by some external agent, and then the agent loses energy by the amount it expends upon the system. By further extending the same considerations we reach the view that energy cannot be created or destroyed, and that the total energy of the universe is a constant quantity. This is the doctrine of the conservation of energy. Kinetic energy is constantly being changed into potential, and vice versa; but besides the forms in which energy has been mentioned, it exists in a variety of other forms which are not so obviously of a mechanical nature. Both potential and kinetic energy may be classified, as follows:

Potential.	Kinetic.
Strain (extension, compression, or distortion).	Motion (translation or rotation).
Electrification.	Vibration.
Magnetization.	Electricity in motion.
Chemical separation.	Heat.
Gravitative separation.	Radiation.

In all wave motions, i.e., in radiation, energy is transferred from one point to another; and at any instant part of the energy of the medium carrying the waves is kinetic and part potential. In heat phenomena all heat effects are due to the addition or withdrawal of energy from the molecules or small portions of the bodies expe-

riencing the effects; the energy of the minute parts is both kinetic and potential in general. The energy of the parts of a gas is almost entirely kinetic. Motion and strain are the obvious mechanical forms of energy, and their equivalence was early recognized, but energetics to-day involves the statements (a) that energy in any form may be changed into energy of any other form, which is a declaration of the correlation and transformation of energy; (b) that, when energy in any form disappears, an exact equivalent of some other form or forms takes its place, which is a declaration of the conservation of energy; and (c) that, when energy undergoes transformation, or transference from one body to another, the process is not completely reversible, but that if some of the energy is recovered in its original form a residual portion reappears in what is called a lower form. This is the *degradation and dissipation* of energy. Both (a) and (b) are commonly implied in the principle of conservation of energy.

Historical Sketch. Although the concept of force as the effort made in doing work, or that of energy as the capability of a body to do work, might either have been made the starting point for a system of dynamics, the former, which was the Newtonian, was first and most completely developed. This seems to have been owing to the fact that force appeals to our so-called "muscular sense," or sense of muscular effort, whereas there is no distinct sense perception of work or energy. When branches of physical science other than mechanics were found to be related to mechanical work with a definiteness that had not before been suspected, the field of energy was widened, and the Huygenian conception became a more familiar one. The first great step of this kind was the recognition of an identity equivalence of mechanical work and of heat effects produced by such work. Experiments by Count Rumford, in 1798, on heat produced by the boring of cannon, and by Sir Humphry Davy, in 1799, on melting of ice by friction, introduced the idea that heat is a form of energy for which there is an exact mechanical equivalent. This proposition, controverting the then accepted theory that heat is material, was too radical to meet with wide acceptance, and the subject received little further development for nearly half a century. It was reasserted by Julius Robert Mayer in a philosophical discussion in May, 1842, but his determination of a definite numerical value for the mechanical equivalent of heat was not made public until 1845. To measure heat, the unit chosen was the "quantity of heat" necessary to raise a unit mass of water one degree in temperature. Taking for the unit mass one gram, and the Centigrade scale for temperatures, the heat unit is called a *calorie* (or sometimes a *water-gram degree*). The unit of work in gravitation measure may be taken as the work of lifting one gram weight a height of one meter, called a gram meter. In the various experiments other units were employed, but we give the results reduced to these. The problem was to determine how many gram meters can produce one calorie and are therefore equivalent to it in energy. This number is called the *mechanical* or, better, the *dynamical equivalent of heat*. It may, of course, be expressed finally in absolute units of work. Mayer's value, 365, was obtained by observing the heat evolved in

compressing air. In January, 1840, James Prescott Joule read a paper before the Philosophical Society of Manchester regarding the thermal and chemical effects of an electric current, which was followed by other investigations in rapid succession, and on Aug. 21, 1843, he communicated to the British Association for the Advancement of Science the result of a most significant investigation, in a paper "On the Relation of Magneto-Electricity, and on the Mechanical Value of Heat." He obtained for the latter 460 gram meters. Then, by allowing the work to be done by weights descending under gravity, and the heat to be produced by the friction of water forced through narrow tubes, he obtained the value 423 gram meters. In November of the same year a Danish engineer, A. Colding, presented before the Academy of Copenhagen the results of experiments upon the heat produced by friction of solid bodies, and expressed the view that the law of conservation of force was a general one. His result for the dynamical equivalent was 370. Although the principle of conservation of energy was suggested almost simultaneously by several physicists, Joule was most indefatigable in the prosecution of his experiments, and within two years he had determined the dynamical equivalent of heat by a variety of methods, the most celebrated of which was the employment of descending weights to drive paddles in a vessel of water, the latter being heated by the friction of the currents in the water produced by the vanes. His paper giving an account of this determination was published in the *Philosophical Magazine* in 1845 and has become classic. In 1847 appeared a discussion of the subject by Helmholtz, entitled "Ueber die Erhaltung der Kraft," which contributed greatly to the establishing of the principle. Between that time and 1860 the whole subject was discussed theoretically and extended experimentally by Helmholtz, Joule, Rankine, Thomson (Lord Kelvin), Clausius, Maxwell, and many others. By 1850 Joule had obtained the value 423.55 gram meters as his best result, and that number stood as the most acceptable value for more than 20 years. In this interval, however, many experiments were made to determine this important quantity by transformations of energy through mechanical, electric, magnetic, and chemical processes, and by 1860 the generally accordant results had not only conclusively demonstrated that heat is a form of energy, but they also demonstrated the conservation of energy. The effect upon scientific investigation was extraordinary. So important a constant is the dynamical equivalent of heat that attempts to determine its value have been made in many ways, including among them various indirect methods in which heat is produced electrically or otherwise than by mechanical work directly; but the most elaborate redetermination by Joule's method of the friction of water by stirring was made in the years 1877 to 1879 by Prof. H. A. Rowland, in Baltimore, Md., U. S. A. His results are, on the whole, the most accurate, and give not only a highly accurate value, but bring out the differences in the value owing to differences in the specific heat of water at different temperatures. They range from 429.8 at 5° C. to 425.8 at 36°, passing through a minimum value of 425.5 at 29°. To express these values in ergs they must be multiplied by 100 times the weight of one gram in dynes at the

place to which the results apply. This weight is numerically equal to the acceleration of gravity in cms. per sec². At Baltimore, $g = 980.05$, and Rowland's mean value of the dynamical equivalent from 20° C. to 35° C. is 425.9 gram meters, or 4.17×10^7 ergs. The value 4.2×10^7 ergs is usually assumed as the mean value, and this is Rowland's value for water at 10° C. The latest determinations give 4.18×10^7 ergs for the 20° calorie. The work of lifting one gram a height of 425.9 meters, or 425.9 grams a height of one meter, against gravity, is exactly sufficient to raise one gram of water from 10° C. to 11° C. in temperature.

Factors.—Energy can be examined only in connection with matter, and the absolute energy of a body cannot be determined; but the changes of its energy can be determined by the work done upon it to increase its energy, or by the work it does in conferring energy upon another body. In all cases two factors are involved in the physical action, and two factors are required in the mathematical expression. For example, in doing the work, the force employed and the distance over which it moves the object are the physical quantities, and their numerical measures, symbolized by F and s , give the product Fs as the mathematical expression. If this work has been done in producing kinetic energy, the mass of the body and the velocity given to it are the physical factors, and half the product of the mass by the square of this velocity, i.e., $\frac{1}{2}mv^2$, is the mathematical expression. When, however, mechanical work is expended in heating a body, then the factors concerning the latter are its specific heat and its rise in temperature. Bodies taken indiscriminately as to physical conditions of strain, electrification, temperature, etc., placed indiscriminately as to position and left free of constraint, except such as results from these conditions, will not in general remain as placed, but will readjust themselves, by transferences and transformations of their energies, always in a way to reduce the potential energy. In this effort at readjustment lie the origin and nature of all changes in the material world. That substances may exist together as placed, it is necessary that one of the factors of the energy possessed by the bodies shall have the same value in all parts of the system. This factor is called "the intensity of the energy. It is for kinetic energy, velocity; for potential energy, force; for heat, temperature; for electrical energy, electromotive force. Whenever one of these magnitudes has different values at different parts of the system, the latter cannot remain at rest, and the appropriate process takes place." (Ostwald.)

Potential and Force. Any region in which work has to be done to move a body from a point A to another point B is called a *field of force*. In such a field the body, when moved from A to B, will gain potential energy equal to the work done upon it and, if allowed to return from B to A by frictionless constraint, will have its potential energy transformed into its equivalent in kinetic energy. The forces of the field may be due to various causes. If to gravitation, the field is called a gravitation field of force; if to electric charges, an electric; if to magnetism, a magnetic field. In every field of force work is done upon the body only if it is of a sort to be affected by the agency in consequence of which the field of force exists.

In a gravitation field it would be matter itself that would be affected; in a magnetic field it would be only a body that would be affected, and . . . Work is expended either upon a body or by it, in bringing it from a point that is without the field to any point in the field, and the amount of energy so required to bring a unit quantity to a given point is called the *potential* at that point. In the gravitation field of force the potential at a point is the work expended in bringing a *unit mass* from infinity to the point; in an electric field it is the work of bringing a *body with unit charge of electricity* to the point. There is, then, a definite potential at a point whether a body is there or not. It is interesting to note that, in Helmholtz's celebrated early discussion of the conservation of energy, the work of transferring any quantity of the kind affected by the field of force from one point to another is the quantity multiplied by the difference of potential between the points. Calling the quantity Q , and the difference of potential V , we have work $= QV$, which is also the change of energy the body undergoes. But the work is also the product of the average force, F , by the distance, s , over which the quantity is transferred: therefore $Fs = QV$, or $F = \frac{QV}{s}$. This is change of energy per unit distance, or the space rate of change in energy.

The limit which the fraction $\frac{QV}{s}$ approaches as s is diminished is the value of the force to move the quantity Q in the direction of s at any point. If $Q = 1$, F is unit force. Unit force, then, might be defined as the space rate of change of potential, and the force upon a body as the space rate of change in energy of the body. This is directly comparable with the Newtonian definition as the time rate of change in momentum. The term "electromotive force," however, is used to express energy, and is equal to and of the same order as the difference of potential it can produce. Since force is the space rate of change in energy, this might be used as a definition of force if the concept of energy precedes it. We might thus dispense with the questionable statement that one body *attracts another*. Two pieces of matter behave as if they attracted each other, but it does not follow that they so attract. We may say, however, that "the part of the energy of a system of two particles of matter of masses m and m' , which depends upon their distance, r , from one another, is measured by $\frac{mm'}{r^2}$, and this is not altered by the presence of other particles." (Tait.) This, indeed, represents our whole knowledge of the subject, and the concept force is unnecessary.

Units. The same unit may be employed to measure work and energy. In the C. G. S. system the absolute unit of work is the *erg*, which is the work of a force of one dyne, exerted along a path one centimeter in length. In the foot-pound-second system the absolute unit is the foot poundal. In gravitation measure the corresponding units are the gram centimeter and the foot pound. When expressed in the fundamental quantities of length, mass, and time, the dimension of energy in mechanical measure is always of the order of the square of a length, multiplied by the first power of a mass, and

divided by the square of a time, or L^2MT^{-2} . (It should be noted that the two lengths which enter this expression are in the *same direction*. A moment of a force has the dimensions L^2MT^{-2} , but the two lengths are at right angles to each other.) By this we may see whether physical quantities represent energy if we observe whether they are expressible in these dimensions. For example, in a gas the pressure per unit area, p , is of the dimensions $L^{-1}MT^{-2}$, and the volume, v , is of the dimensions L^3 ; then the product pv has the dimensions L^2MT^{-2} , and it may be shown that the work done in compressing a gas is the product of the pressure and the change in volume. In heat the unit is the *calorie*, which equals 4.2×10^7 ergs. The absolute unit of energy of an electric current is also the erg, but the practical unit is the work of transferring a coulomb of electricity over one volt difference of potential, and is called a volt coulomb, or one joule; its mechanical value is 10^7 ergs. The calorie therefore equals 4.2 joules, or one joule equals .24 calorie.

Dissipation of Energy, Irreversibility, Entropy. If a body is changed from one state to another by a series of operations, and then, when subjected to these operations in an opposite sense and in exactly the reverse order, the body returns to its first state, the whole cycle of operations is called a *reversible process*. When the transformations cannot be repeated in the reverse order, or if, when reversed, the agencies are not equal in magnitude and opposite in sign to those which occur at the same points in the direct process, the transformation is said to be *irreversible*. According to Planck, the most immediate criterion of irreversibility of a process consists in the proof of a function completely determined by the instantaneous condition of the system, which possesses the peculiarity that it changes during the whole process always in the same sense—perhaps increases. Suppose a body in a state A as to its temperature and quantity of heat, to be changed by any small quantity of heat h at the temperature t , the ratio of change in heat to the temperature at which the change is effected being $\frac{h}{t}$ and let a succession of such changes bring the body to a state B. If, now, changes be effected in the opposite sense in exactly the reverse order, and when the sum of the reversed quantities $\frac{h}{t}$ equals the sum of the direct ones, the body has regained the state A, the cycle through which it has passed is a *reversible* one. Then "the limit which the sum of the quantities $\frac{h}{t}$ from the state A to the state B approaches is a constant quantity which depends only on the pressure, volume, and temperature at the state A and the state B, and not all upon the intermediate stages; there is a distinct and measurable physical property of a body, which is characterized by the peculiarity that it increases or diminishes as heat enters or leaves the body, but remains constant when there is no communication of heat. This quantity is called the *entropy*," $\frac{h}{t}$ being the measure of change in it. (Hastings and Beach.) Planck shows that electromagnetic radiation, which may now be considered the form in which energy is transmitted through the ether of space,

under conditions termed by him "natural radiation," is attended by a constant increase of entropy in the system of bodies emitting and receiving the rays. By the above criterion, then, such radiation is not a reversible process. Suppose a quantity of heat h to pass from a body at temperature t_1 to another at the temperature t_2 ; the entropy of the former is diminished by $\frac{h}{t_1}$, that of the latter increased by $\frac{h}{t_2}$, and since t_1 exceeds t_2 , in order that heat shall so pass, the entropy of the two is greater than at first by $h \left(\frac{1}{t_2} - \frac{1}{t_1} \right)$. Therefore all transfers of heat by radiation and conduction in a system of bodies increase the entropy of the system, and hence "the entropy of the universe tends to a maximum." (Clausius.) In any irreversible process, then, a portion of the energy expended in some of the operations cannot be regained for a similar purpose; they are available only for purposes requiring energy of a lower order. No known natural process is exactly reversible, a certain portion of the energy being always dissipated as heat. It follows that, as energy is constantly undergoing transformation, there is a constant degradation of energy to the final unavailable form of uniformly diffused heat.

Sources of Energy; Matter; Ether. Of the ultimate nature of energy, as of that of matter, we are ignorant; nor do we know of energy by direct observation, except as associated with matter. It is the change of energy, either as to quantity or form, that is scrutinized and measured, and such change is continually occurring as energy passes from body to body; but the condition of a body totally devoid of energy is a subject of speculation only. Terrestrial energy available to man may be classified as energy of fuel, food, head of water, wind, tides, chemical action, solar radiation. These, with a partial exception in the case of the fifth and sixth, are all traceable to the sun. The earth receives $\frac{1}{200,000,000}$ part of the total solar radiation, and the rate at which radiant energy from the sun is expended upon a unit area of the earth's surface is called the solar constant. From tests conducted above the clouds, notably at Mont Blanc and at Mount Whitney, this constant has been determined. From the latter observations Professor Langley concluded "that in view of the large limits of error we can adopt *three calories* as the most probable value of the solar constant; by which I mean that at the earth's mean distance, in the absence of its absorbing atmosphere, the solar rays would raise one gram of water three degrees centigrade per minute for each normally exposed square centimeter of its surface." Subsequent determinations from observations at widely separated stations not only reduced this estimate but show that the rate of emission of energy by the sun fluctuates between maximum and minimum values. Observations under the auspices of the Smithsonian Institution, extending from 1902 to 1913, showed that the value ranged between 1.80 calories and 2.10 calories. The mean value, 1.933 calories per minute per square centimeter, is given by Dr. C. G. Abbott. (Consult *Science*, vol. xxxix, March 6, 1914.) This is 1.347×10^9 ergs, or 13.7 gram meters per second to the square centimeter of surface. As this is trans-

mitted at the rate of 300,000,000 meters per second, it represents the energy of solar radiation present in a column of ether near the earth one square centimeter in cross section and 300,000,000 meters in length. Owing to absorption by clouds and the atmosphere, the portion actually reaching the ground surface of the earth is reduced by one-third to one-half.

Although nearly all terrestrial energy may be ascribed to solar origin, the earth also is a radiant body far above interplanetary space in temperature, and various theories have been evolved to account for the maintenance of the sun's heat as well as that of the earth. In the main they imply the conversion of mechanical or of chemical energy into heat. Since, however, it is neither possible nor necessary to postulate any definite total amount of energy in the universe, it is only necessary to find a competent process of energy change which will account for the continuance of radiant energy in the face of the enormous rate at which it is dissipated. With the beginning of the twentieth century came the discovery of radioactive substances which emit rays conveying energy with small diminution in the mass of the body from which they proceed. (See RADIOACTIVITY.) To account for this has required an assumption of energy associated with the atom far beyond anything heretofore conceived of, and a profoundly modified view both of the structure of the atom and of transformations of matter has resulted. A theory due to Rutherford and Soddy, that has been used most effectively, is "that the atoms of the radio-elements suffer spontaneous disintegration, and that each disintegrated atom passes through a succession of well-marked changes, accompanied in most cases by the emission of α -rays," which are the rays associated with heat effects. In the course of disintegration which the atom is thus assumed to be undergoing, the process of radiation from within the substance is attended by an absorption of the radiation in large measure by the body itself, its own temperature being thereby kept higher than that of the medium surrounding it. The heating effect of radium is closely proportional to its radioactivity as measured by the α -rays. The heat radiated from radium is about 100 gram calories per gram per hour, and from any radioactive matter it is larger in comparison with that due to any known chemical reaction.

It has been suggested that from the radioactivity of the most elemental constituents of the sun, and also from the aggregate radioactivity of substances composing the earth, might come the energy supplied by both the sun and the earth for countless ages. This, like other theories, can as yet be regarded only as a speculation. Two and a half parts in a million, by weight, of radium in the sun would account for its present rate of emission of energy, and the presence of a very small percentage of uranium or other equally active substance distributed throughout the earth would be sufficient even to raise the earth from a cold condition to a hot one. Rutherford shows that the radioactivity of ordinary bodies is of an order high enough to balance the loss of the earth's heat into space. The radiation of energy has of late been much discussed in connection with the subject of relativity, from which the proposition results that the energy sent out by a body does not flow out continuously, but is

emitted explosively in integral numbers of a fundamental unit of energy. This idea is at the base of what is called a *quantum hypothesis* of radiation. See RELATIVITY.

Besides papers cited above, the following works, among many others, are devoted wholly or in part to energetics: Maxwell, *Matter and Motion: Theory of Heat* (London and New York, 1891); Tait, *Recent Advances in Physical Science* (London, 1876); id., *Properties of Matter* (Edinburgh, 1885); Thomson (Lord Kelvin), *Popular Lectures and Addresses*, vol. ii (London, 1894); Dolbear, *Matter, Ether, and Motion* (Boston, 1892); Joule, *Scientific Papers* (2 vols., London, 1884-87); Rowland, *Scientific Papers* (Baltimore, 1902); Tait, *Thermodynamics* (Edinburgh, 1877); Popper, *Die physikalischen Grundsätze der elektrischen Kraftübertragung* (Vienna, 1883); Helm, *Die Lehre von der Energie* (Leipzig, 1877); Planck, *Das Princip der Erhaltung der Energie* (ib., 1877; 2d ed., 1908); Clausius, *Die mechanische Wärmetheorie* (Brunswick, 1876-91); Holman, *Matter, Energy, Force, and Work* (New York, 1898); Nyssens, *Essai de philosophie précise* (Bruxelles, 1908); Ostwald, *Die Energie* (2d ed., Barth, 1912); Soddy, *Matter and Energy* (London, 1912).

ENERGISM (from Gk. *ἐνεργός*, *energós*, active, from *ἐν*, *en*, in + *ἐργον*, *ergon*, work). The name given by some recent philosophical writers to the neo-Aristotelian view that the chief end of human life is not pleasure, but due activity of the distinctively human functions, or, generalizing the statement, "the goal at which the will of every living creature aims is the normal exercise of the vital functions which constitute its nature. Consult Paulsen, *System der Ethik* (Berlin, 1894; Eng. trans., 1899). See EUDÆMONISM.

Energism is also the term used to designate the type of metaphysical theory which regards energy as the ultimate reality. Ostwald is the most recent distinguished exponent of metaphysical energism. Consult: Ostwald, *Vorlesungen über Naturphilosophie* (Leipzig, 1905); *Natural Philosophy* (New York, 1910); *Der energetische Imperativ* (Berlin, 1912).

EN'ERGŪ'MENS (Lat. *energumenus*, from Gk. *ἐνεργούμενος*, *energoumenos*, demoniac, pres. p. of *ἐνεργεῖν*, *energeîn*, to work in, from *ἐν*, *en*, in + *ἐργεῖν*, *ergeîn*, to work, from *ἐργον*, *ergon*, work). A class of persons, suffering from some physical ailment, who in the early ages of the church were believed to be possessed by evil spirits and were placed under the special care of exorcists, yet allowed a certain amount of participation in religious services. Catechumens included in this class could not be baptized, except when at the point of death; while those who became deranged after baptism might be allowed to commune. Both classes had a home in the church and during the services occupied the porch along with lepers and other defiled persons, but at the conclusion of the service received the spiritual benediction.

ENERGY. See ENERGETICS; MECHANICS.

ENERGY OF PLANTS. The energy relations of the fully autotrophic plants differ somewhat from those of the partially or fully heterotrophic forms, so it is well to discuss the two types separately. In the green plants, as autotrophic forms, the energy exchanges and transformations have been most fully studied in the thin green leaf. The main source

of energy for this organ is radiant energy. In the temperate zone, with direct sunlight, as much as one calorie of radiant energy per square centimeter per minute falls upon the leaf. Of this approximately 0.75 of a calorie is absorbed. A minor source of energy for the green leaf, and probably one of little physiological importance, is that from the surrounding air through thermal emissivity. This exists only when the leaf has a lower temperature than the surrounding air, a condition generally existing in transpiring parts during darkness and in light when the transpiration power of the air is great. The radiant energy absorbed by a green leaf, if transformed to heat and retained as such, is often sufficient to raise the temperature of the leaf 30° C. per minute. From this it is evident that the leaf must have some means, on penalty of life, of dispersing this energy. There are four possible uses of it—vaporization of water or transpiration, photosynthesis, raising the temperature of the leaf, and loss to the air through thermal emissivity. By far the greater part is used in transpiration, photosynthesis consumes from 0.6 to 6 per cent of it, while the amount used to raise the temperature of the leaf or lost by thermal emissivity is generally still less. The latter loss exists only when the leaf maintains a higher temperature than that of the surrounding air, under illumination with transpiration not excessive. Loss of heat by thermal emissivity is thought to be of considerable importance as a cooling factor in desert forms with low capacity for transpiration. The energy rendered potential by photosynthesis can again be released by respiration. The storage of energy in photosynthesis in the green leaf greatly exceeds the release by respiration, and, of course, the same holds for the synthesis and oxidation of carbohydrates. This means a continual accumulation of organic material and energy through the activities of the green leaf. Such a material and energy accumulation is of great cosmic significance, for it renders possible the existence of all heterotrophs, plant and animal, also the existence of non-chlorophyllous parts of the same plant at all times and the chlorophyll parts during darkness. Here, too, we find the source of the energy that is stored in coal, wood, and peat.

The nonchlorophyllous parts of green plants may be considered with the heterotrophs. In the case of heterotrophs the main source of energy is that existing as potential energy in the nutrients taken up. This energy is made available for physiological work by the oxidations involved in fermentation and respiration. A minor source is that taken up by thermal emissivity from the air, a source existing only under conditions mentioned above. The uses made of the energy are similar to those in the green leaves except for the lack of photosynthesis in these forms. Another energy loss is the excretion of incompletely oxidized materials. This might be compared to the loss from the foliage leaf by translocation to other regions of the plant. In all living plants energy manifests itself in the form of osmotic pressure and imbibitional force.

The energy in plants undergoes various transformations conforming to the law of conservation of energy. The potential energy of nutrients is transformed to kinetic energy by respiration or fermentation (q.v.). This, in turn,

may carry on physiological work or become mechanical energy. It may end up as heat, electricity (q.v.), or even light. (See RESPONSE IN PLANTS; PHOSPHORESCENCE.) Similarly the radiant energy (especially certain portions of the light) absorbed by green plants goes through a series of transformations. Some believe it first becomes electrical energy, then chemical energy reducing carbonic acid, and then potential energy stored in the organic foods formed. After that it may go through the transformations mentioned above.

ENESCO, GEORGES (1881–). A Rumanian composer, born at Cordareni, Rumania, Aug. 7, 1881. When only four years old, he began to play the violin and made such astonishing progress that at the age of seven he was admitted into the violin class of Hellmesberger at the Vienna Conservatory. Here he also studied harmony and counterpoint with Fuchs and tried his hand at original compositions. He remained in Vienna for six years. In 1894 he went to Paris, where he entered the Conservatory, studying violin with Marsick, and composition with Fauré and Massenet. In 1899 he won the first prize for violin playing. As early as 1897 he gave a concert of his own works of chamber music which attracted the attention of Colonne, who in the following year brought out the young composer's *Poème roumaine*. Even these early works show a strong individuality and remarkable inventive power. While still in Vienna, Enesco became infatuated with the works of Wagner and Brahms, who always have remained his ideals and probably saved him from the influence of modern French impressionism. The promise held out by the first works was fulfilled in the later ones, especially in his first symphony in E flat, op. 13 (1909), which carried the fame of its author beyond France into Germany and the United States. His other works include a *Fantaisie pastorale*, a symphony for wind instruments, a suite for orchestra, 3 *Rhapsodies roumaines*; a suite for piano and violin, two sonatas for piano and violin, a quintet for piano and strings. Although he rarely appears as a performer, he is regarded in Germany as one of the foremost violinists. He is also a pianist, organist, and cellist of no ordinary ability.

ENFANTIN, ănfăntin', BARTHELEMY PROPER (sometimes called PERE ENFANTIN) (1796–1864). A French social reformer, born in Paris. He was educated at the Ecole Polytechnique, whence he was expelled in 1814 for complicity in the Montmartre demonstrations of former pupils of the Ecole against the Allies. Subsequently he was connected with banking firms at St. Petersburg and Paris. After 1825 he became a leading representative of the Saint-Simonist teachings. In this rôle he was associated with Bazard. He differed with Bazard, however, on the marriage question in that he openly advocated free love. For this he was sentenced to one year's imprisonment and a small fine. Released after a few months, he went to Egypt, where he could have entered the service of the Viceroy, Mehemet Ali, if he had professed Mohammedanism. After his return to France he became a postmaster near Lyons. He was a member of the scientific commission entrusted by the government with the preparation of a report on Algeria in relation to French colonization. On this subject he wrote *Colonisation d'Algérie* (1843). In 1845 he became a director of the Paris and Lyons

Railway. The volumes *Traité d'économie politique* (1830; Ger. trans., 1905) and *Religion Saint-Simonienne* (1831) constitute his chief published work; his influence depended largely upon his ability as an orator and propagandist. His writings, including his correspondence, appeared with those of Saint-Simon in the Paris edition of 1865-78 (47 vols.). Consult G. Weill, *L'Ecole Saint-Simonienne, son histoire, son influence, jusqu'à nos jours* (Paris, 1896).

ENFANTS DE DIEU, ən'fän' də dyē (Fr., children of God). A name given to the Camisards (q.v.).

ENFANTS PERDUS, pār'du' (Fr., lost children; Eng. equivalent, "a forlorn hope"). The term is a military expression, meaning the officers and men who were appointed or who volunteered to lead the way in some especially dangerous assault.

ENFIELD. A market town in Middlesex, England, 11 miles north of London, noted for its Royal Small Arms Factory, where the celebrated Enfield rifle of the British army was manufactured (Map: London, B 7). (See **SMALL ARMS**.) The town contains the remains of a royal palace in which Edward VI kept his court now used as a school. Isaac D'Israeli was born at Enfield; Keats and Captain Marryat were educated there, and Charles Lamb was a resident from 1827 to 1833. Pop., 1901, 42,700; 1911, 56,344.

ENFIELD. A town in Hartford Co., Conn., 15 miles (direct) north of Hartford, on the Connecticut River, and on the New York, New Haven, and Hartford Railroad (Map: Connecticut, E 2). It has carpet factories, steam brickworks, and establishments for the manufacture of undertakers' supplies, filter presses, and shoddy. Enfield has a Carnegie library and is the centre of extensive tobacco-growing interests, and there are several houses engaged in tobacco sorting. Within the limits of the town is . . . a community of Shakers. The government is administered by town meetings. Pop., 1900, 6699; 1910, 9719; 1914 (U. S. est.), 11,006.

ENFIELD RIFLE. An army rifle, which derives its name from the place of its manufacture in England. It was invented in 1855 and remained in general use until the adoption of the breechloader in 1867. During the Civil War in the United States (1861-65) many Enfield rifles were used by the United States army, because not enough Springfield rifles could be obtained. It was also in very general use among the Confederate forces.

ENFILADE' (Fr., string, from *enfiler*, to thread, from ML. *infilare*, to string, from *in*, in + *filum*, thread). Fire directed at an enemy from the flanks, penetrating his entire length of line. It is the most effective fire possible, owing to the larger target presented. Positions capable of being enfiladed are untenable, no matter what other advantages they may possess. In intrenchments protection against enfilade fire is obtained by constructing *traverses*, banks of earth, at right angles to the line of intrenchment. The English troops in South Africa, in the Boer War of 1899-1901, were frequently enfiladed, the topography of the theatre of operations greatly aiding the Boers.

ENGADINE, en'gä-dēn'. A famous valley in Switzerland, in the Canton of Grisons (q.v.), second only to the Valais in length (Map: Switzerland, D, E 2). It extends northeast for over

60 miles along the banks of the Inn, from the foot of Mount Maloja, or Maloggia, to the village of Martinsbruck; area, 653 square miles. It is divided into two portions—that towards the southwest, called the Upper Engadine, which has an average elevation of about 5000 feet, and that towards the northeast, the Lower Engadine. There are numerous glaciers. The climate, while cold, is singularly . . . the Upper Engadine being famous as a health resort, the most frequented place being Saint-Moritz, 6037 feet. The vegetation of the Upper Engadine is abundant and the scenery is remarkably picturesque. The Lower Engadine is narrower, less cultivated, but more picturesque. It is practically unknown to the tourist; most of its villages rest on steep terraces. Pop., 1900, 11,712 (mostly Protestants); 1910, 12,193. The natives speak a Rhaeto-Romanic dialect known as Ladin.

ENGAGEMENT, MILITARY (from *engage*, Fr. *engager*, from ML. *inviadiare*, to pledge, from *in*, in + *vadium*, pledge, from Lat. *vas*, surety). Active contact with an enemy. The term is generally applied to minor battles, or encounters in which only parts of the contending armies are engaged, or contacts other than a pitched battle. Under modern conditions a battle is, more than ever before, the decisive factor of a campaign, the manœuvring for positions of advantage resulting in engagements of more or less frequency and variety. See **BATTLE**; **STRATEGY**; **TACTICS, MILITARY**.

EN-GEDI, ən-gē'dī (Heb. *'en-gedi*, fountain of the kid, Ar. *'Ain-Jidi*). The name of a wilderness, forming the eastern part of the wilderness of Judah, and of an oasis with a spring of warm water on the west shore of the Dead Sea, where at various times a community has flourished (Map: Palestine, E 5). It is assigned to the tribe of Judah in Josh. xv. 62. David fled to the wilderness of En-gedi from Saul and was pursued thither by the King (1 Sam. xxiii. 29-xxiv. 22). In the reign of Jehoshaphat the Ammonites, Moabites, and Edomites gathered here preparatory to invading Judah, according to 2 Chron. xx. 2. The vineyards of En-gedi are referred to in Canticles (i. 14). Pliny (*Nat. Hist.*, v, 17) mentions the place as a ruin in his day, and now the district is tenanted only by a few Arabs of the tribe of the Reshaid. Consult Gautier, *Autour de la mer Morte* (Paris, 1901), and Abel, *Une croisière autour de la mer Morte* (ib., 1911).

ENGEL, ɛŋ'el, CARL (1818-82). A German-English writer on music. He was born near Hanover, studied the pianoforte under Hummel, and in 1850 settled in London, where he attained success as a teacher of music and writer on musical subjects. He owned a large collection of rare musical instruments, many of which were given after his death to the South Kensington Museum, with which he had been connected for many years. His books on the history of musical instruments and the ancient nations are standard works. Among them may be mentioned: *The Music of the Most Ancient Nations* (1864); *An Introduction to the Study of National Music* (1866); *Musical Instruments of All Countries* (1869); *Resuscitates into the Early History of the Violin Family* (1883).

ENGEL, ERNST (1821-96). A German statistician, born in Dresden. He studied mining engineering at Freiburg and Paris. After act-

ing as member of the Saxon commission for the investigation of industrial and labor conditions, he became in 1850 director of the Royal Saxon Statistical Bureau in Dresden. His work here was mainly in improving the methods of statistics and popularizing the results. In 1858 he resigned to assume charge of the Saxon Mortgage Insurance Company, but returned in 1860 to the public service as director of the Prussian Statistical Bureau. In this office he remained until 1882, when failing health caused him to retire. He was known in professional circles as one of the most capable and energetic of modern statisticians, and his contributions to the methods of administrative statistics were considerable. His investigations into the household expenses of the laboring classes were particularly valuable. Consult *Bulletin de l'Institut International de Statistique*, vol. x (Rome, 1897). Engel's chief works are reprints of contributions to the *Zeitschrift des statistischen Bureau*s and include: *Die Methoden der Volkszählung* (1861); *Land und Leute des preussischen Staates* (1863); *Das Zeitalter des Dampfes* (2d ed., 1881).

ENGEL, FRANZ (1834-). A German traveler, born at Rüböl, Mecklenburg-Schwerin. From 1857 to 1863 he made a tour through South America, accounts of which he published in the interesting and valuable volumes entitled *Studien unter den Tropen Amerikas* (2d ed., 1879) and *Aus dem Pflanzerstaate Zulia* (1881). He produced the *Landwirthschaftliche Jahrbücher*, vols. i-xxv (1872-96).

ENGEL, JOHANN CHRISTIAN VON (1770-1814). An Hungarian historian, born at Leutschau, Hungary, and educated at Göttingen, where he studied under Heyne, Schlözer, and others. He was ennobled in 1812. His works are thoroughly full of varied and extensive information, and valuable for their time. Engel was a pioneer as regards the history of Hungary. His principal works are entitled *Geschichte des ungarischen Reiches und seiner Nebenländer* (5 vols., 1797-1804) and *Geschichte des Königreichs ungarn* (5 vols., 1814-15).

ENGEL, JOHANN JAKOB (1741-1802). A German dramatist and critic, born at Parchim. He was educated at Rostock, Bützow, and Leipzig, and held various posts, including the directorship (with Ramler) of the Berlin Theatre (1787-94), which was given him on the strength of his essay "Ideen zur Mimik." He wrote much on the theory of art and aesthetics, including, in collaboration with Mendelssohn and others, the *Philosoph für die Welt* (2 vols., 1775-77), and *Anfangsgründe einer Theorie der Dichtungsarten* (2d ed., 1804). His *Herr Lorenz Stark*, a work of fiction first published in Schiller's *Horen* (1801), was distinguished by humor and effective dialogues. Although his dramas are only mediocre, he sympathized with Lessing's efforts to make the German drama a genuine expression of national life. His *Sämtliche Schriften* were published at Berlin (2 vols., 1801-06; new ed., 14 vols., 1851).

ENGEL, JOSEPH (1816-99). An Austrian anatomist, born in Vienna. In 1844 he was appointed to the chair of anatomy at Zurich and subsequently to that of physiology also. He became professor of pathological anatomy at the University of Prague in 1849 and from 1854 to 1874 was a professor of anatomy in the

Josephsakademie for physicians and surgeons at Vienna. His contributions to the development and systematization of anatomical science were considerable. In addition to a large number of uncollected articles, he wrote a *Lehrbuch der pathologischen Anatomie* and a *Kompendium der topographischen Anatomie* (1859).

ENGEL, KARL DIETRICH LEONHARD (1824-). A German musician and author. He was born in the Grand Duchy of Oldenburg and went to Russia in 1842 as a violin virtuoso. Here he was very successful, and at the age of 22 was appointed a member of the Imperial orchestra at St. Petersburg, of which body he subsequently became concertmaster. In 1869 he settled at Dresden. His writings, principally on the legend of *Faust*, include: *Deutsche Puppenkomödien* (vols. i-xii, 1874-93); *Das Volksschauspiel Doktor Johann Faust* (2d ed., 1882); *Zusammenstellung der Faustschriften vom 16. Jahrhundert bis Mitte 1884* (2d ed., 1884); *Die Don Juan Sage auf der Bühne* (2d ed., 1888). His musical compositions include a concerto in B minor and the unique and humorous fantasy entitled *Jüdischer Carneval*.

ENGELBERG, ɛng'el-bɛrk. A health resort in the Canton of Unterwalden, Switzerland, in the northeast part of the Engelberg valley, 3356 feet above sea level and 14 miles south of Lucerne (Map: Switzerland, C 2). Here is located a Benedictine monastery, founded in 1120, with a library of 20,000 volumes, including many incunabula, besides manuscripts. There is an eleventh-century Catholic gymnasium connected with the abbey. The chief industry is cheese manufacture. Pop., 1900 (including a number of adjacent hamlets), 1976; 1910, 2434.

ENGELBERT, ɛng'el-bɛrt (c.1250-1331). A Benedictine author, born in Völkersdorf, Styria. He was educated at Prague and Padua, and was abbot of Admont in Styria from 1297 to 1327. He is noted chiefly for his Latin history of the Roman Empire, entitled *De Ortu, Progressu et Fine Imperii Romani*, which has been frequently republished. Several of his other productions were published in the *Thesaurus Anecdotorum Novissimus* (1721) and in the *Bibliotheca Asctica Antiquo-nova* (1723-25).

ENGELBERT I, ɛng'el-bɛrt (c.1185-1225). Saint and Archbishop of Cologne. He was born at Berg, of noble origin, was excommunicated in 1206 but reinstated in 1208, and became Archbishop of Cologne at the age of 31. He was one of the foremost ecclesiastical rulers of his day, a patron of agriculture, industry, and art, an excellent administrator, and a sworn enemy to the excesses perpetrated by the feudal barons. He brought about a complete reorganization of the electorate. During the absence of the Emperor Frederick II in Italy after 1220 he was administrator of the Empire as guardian of Henry VII, whom he crowned in 1222 and whom he wished to marry to an English princess. In consequence of an accusation of maladministration which he had brought against his nephew, he was waylaid and slain by hirelings of the latter while on his way to consecrate a church. He was never formally canonized, but he is commemorated as a martyr on November 7. Consult Stoffel, *Engelbert der Reichsverweser* (Elberfeld, 1893).

ENGELBRECHT, ɛng'el-brɛkt, THEODOR (1813-92). A German physician and pomol-

ogist. He was born near Brunswick. He practiced medicine in Brunswick and in 1844 became professor of physiology in the University there. In 1862 he induced the government to establish the Pomological Institute, and he was the first president of the German Pomological Society (1880-89). His principal work is *Deutschland's Aepfelsorten* (1889).

ENGELBRECHT, THEODOR HEINRICH (1853-). A German geographer, born at Obendeich, near Glückstadt, in Schleswig-Holstein, and educated at Leipzig and Strassburg. In 1911 he received an honorary doctor's degree from the University of Breslau. A member of the *Frei-Konservativ* party, he was elected to the House of Deputies in 1895. He wrote: *Die Landbauzonen der aussertropischen Länder* (3 vols., 1898-99), a work of the utmost importance for the study of European agriculture; *Die geographische Verteilung des Getreidepreises* (1903-08), of which the first volume dealt with the United States in 1862-1900 and the second with India in 1861-1905; *Bodenbau und Viehstand in Schleswig-Holstein* (1905).

ENGELBRECHTSEN, ɛng'el-brɛkt'sɛn, or **ENGELBERTSZ, ɛng'el-bɛrts**, CORNELIS (1468-1533). A painter of the early Netherlands school, born at Leyden. It is not known under whom he studied, and details of his life are lacking. Owing to the destruction of most of his pictures during the Reformation, only two well-authenticated works of large dimensions from his brush remain. These are the altarpieces respectively representing the "Crucifixion" and the "Pietà," in the Museum of Leyden. They are somewhat stiff in composition and dry in color, but show realistic tendencies and a love of the fantastic. Other works, in the museums of Amsterdam, Antwerp, London, Berlin, and New York, have been attributed, with some probability, to him. Engelbrechtsen became known chiefly through his pupils Lucas van Leyden and Aartgen van Leyden.

ENGELHARD, ɛng'el-härt, WILHELM (1813-1902). A German sculptor and painter. He was born at Grünhagen, near Lüneberg, Prussia, and studied sculpture at Hanover, with Thorvaldsen at Copenhagen, and with Schwanthaler at Munich. In 1857, at the request of George V, King of Hanover, he executed the famous frieze in the Palace representing the story of the *Edda*—a colossal work dealing with the main features of the Saga, rich in sculptural effects. His other works include the "Archangel Michael," at the Military School of Gross Lichterfelde, near Berlin; the "Lorelei," in the Bremen Museum; and the colossal statue of "Odin Enthroned," behind the provincial museum at Hanover. He is represented by other statues at Munich, Rome, Hanover, and Berlin.

ENGELHARDT, GEORG VON (1775-1862). A Russian statesman and author. He was born at Riga and at the age of 15 went to St. Petersburg, where, in 1796, he became an employee in the Department of Foreign Affairs. In 1801 Alexander I appointed him Undersecretary of State in the then newly created Imperial Council. In 1811 he became director of the Pedagogical Institute, and in 1816 he was transferred in the same capacity to the lyceum at Tsarskoye Selo, whence, however, he was removed in 1823 because of his pronounced liberalism. He was editor of the *Russische Landwirthschaftliche Zeitung* from 1838 to 1852,

and published *Russische Miscellen zur Kenntniss Russlands und seiner Bewohner* (4 vols., 1828-32) and the manuscript journals of Wrangel the explorer, in the work entitled *Reise langs der Nordküste von Sibirien und auf dem Eismeer* (1839).

ENGELHARDT, MORITZ VON (1779-1842). A Russian naturalist. He was born in Esthonia and was educated at the universities of Leipzig and Göttingen and the mining school at Freiberg. In company with Karl von Raumer he traveled through central Europe and in 1811 he undertook a journey through the Crimea and the Caucasus and in 1818 through Finland. The results of the latter tour were published in the work entitled *Geognostischer Umriss von Finland*, vol. i of an elaborately projected *Darstellung aus dem Felsgebäude Russlands* (1821). From 1820 to 1830 he was professor of mineralogy at Dorpat, and in 1826 he entered upon those extensive travels through Russia in the course of which he discovered the vast deposits of gold, platinum, and diamonds described in his famous reports published at Riga in 1828 and 1830. His other literary productions include a description of his first extensive tour, published by him jointly with his companion Raumer in the works respectively entitled *Geognostische Versuche* (1816) and *Geognostische Umrisse* (1817).

ENGELHARDT, VASSILI PAVLOVITCH, BARON (1828-). A Russian astronomer, born in Kustovitchi (Grodno), of an ancient noble family. He was educated at St. Petersburg and in 1847-53 was in governmental service. In 1872 he built an important astronomical observatory in Dresden. In 1903 new buildings were erected at Kazan to house the instruments at Dresden which the Baron gave in 1897 to the University of Kazan. He published *Observations astronomiques faites à Dresde* (3 vols., 1886, 1890, and 1895).

ENGELMANN, ɛng'el-män, GEORGE (1809-84). An American botanist. He was born at Frankfort-on-the-Main, was educated at the universities of Heidelberg, Berlin, and Würzburg, and became established as a physician at St. Louis, Mo., in 1835. In 1836 he began the publication of the newspaper *Das Westland*, at one time well known through its excellent descriptions of Western life and manners. It was, however, as a botanist that Engelmann became widely celebrated. Although the greatest authority on the North American vine and cactus, Engelmann also gave considerable attention to other species of plants. His reports of his discoveries and to the government. He was the first president of the St. Louis Academy of Science; and his valuable botanical collection, so important in establishing the nomenclature of numerous botanical species of America, is now in Shaw's Botanical Gardens, St. Louis. His publications include *Systematic Arrangement of the Species of the Genus Cuscuta* (1859) and *The Oaks of the United States* (1876).

ENGELMANN, ɛng'el-män, JOHANNES (1832-). A Russian jurist, born at Mitau, Courland, and educated at the University of St. Petersburg. He was professor of Russian law at Dorpat from 1860 to 1899. After 1887 his lectures, which had previously been given in German, were delivered in the Russian language. These lectures, delivered during a period

of nearly 40 years, covered a wide field and contributed greatly to the advancement of the science of jurisprudence in Russia. His works include: *Die Verjährung nach russischen Privatrecht* (1867; in Russian, 1868); *Die Zwangsvollstreckung auswärtiger richterlicher Urteile in Russland* (1884); *Das Staatsrecht Russlands* (1888).

ENGELS, ɛng'els, FRIEDRICH (1820-95). A German socialist, born in Barmen, Prussia. He was an apprentice at Bremen and Berlin and subsequently became connected with manufacturing interests in Manchester, England. In 1814 he was a collaborator on the *Deutsch-französische Jahrbücher*, issued at Paris by Karl Marx (q.v.) and Arnold Ruge (q.v.). From 1846 he was associated with Marx in the Communistic League, a precursor of the International. Afterward (1848-49) he was an editor of Marx's *Neue Rheinische Zeitung* at Cologne, participated in the revolutionary movement led by Struve and Hecker in Baden in 1848-49, and was a manufacturer at Manchester (1850-69). He was an assistant of Marx in the extension of social democracy and was secretary for Portugal, Spain, and Italy in the general council of the International. Besides collaborating with Marx in the authorship of the famous *Communist Manifesto* and editing the second and third volumes of Marx's *Das Kapital* and the third and fourth editions of the first volume of the same work, he is author of: *Die Lage der arbeitenden Klassen in England* (1845; Eng. trans. by Florence Kelley Wischniewetzky, *The Condition of the Working Classes in England in 1844*, 1887; 1892); *Herrn Eugen Dührings Umwälzung der Wissenschaft* (1878; 4th ed., 1901; Eng. trans. by Austin Lewis, *Landmarks of Scientific Socialism, "anti-Dühring,"* 1907); *Der Ursprung der Familie, des Privateigentums und des Staates* (1884; 8th ed., 1900; Eng. trans. by Ernest Untermann, *The Origin of the Family, Private Property, and the State*, 1910); *Ludwig Feuerbach und der Ausgang der klassischen deutschen Philosophie* (1888; 3d ed., 1903; Eng. trans. by Austin Lewis, *Feuerbach, the Roots of the Socialist Philosophy*, 1903); *Entwicklung des Sozialismus von der Utopie zur Wissenschaft* (4th ed., 1891; Eng. trans. by Edward Aveling, *Socialism Utopian and Scientific*, 1892, and 3d ed., 1911). Consult: Dawson, *German Socialism* (3d ed., New York, 1899); the biography of Engels by Sombart (Berlin, 1895); Karl Kautsky, *Engels: sein Leben, sein Wirken, seine Schriften* (Berlin, 1895; Eng. trans. by M. W. Simons, *Friedrich Engels: His Life, his Work, his Writings*, Chicago, 1899).

ENGERTH, ɛng'ert, EDUARD VON (1818-97). An Austrian historical and portrait painter. He was born at Pless, Prussian Silesia, and studied under Kupelwieser at the Vienna Academy, where, in 1845, he obtained the grand prize, which gave him six years' study in Rome. In 1854 he was appointed director of the Prague Academy and studied under Kupelwieser at the Vienna Academy; in 1871, director of the Belvedere Gallery, the catalogue of which he published (1862-86); and in 1874, rector of the Academy. His most celebrated picture is entitled "Seizure of King Manfred's Family after the Battle of Benevento" (Art Museum, Vienna). The colossal painting entitled "The Victory of Prince Eugene at Zenta" (Imperial Castle at Ofen) was also very popular, although somewhat conventional in conception. Engerth frescoed the church at

Alt Lerchenfeld after the cartoons of Führich, painted numerous portraits, and decorated the new Vienna Opera House with a series of paintings from "The Marriage of Figaro" and "Orpheus."

ENGERTH, WILHELM, BARON (1814-84). An Austrian engineer, brother of the preceding. He was born at Pless, Prussian Silesia, studied architecture at the Polytechnic Institute and at the Academy of Arts, Vienna, and in 1844 was appointed professor of mechanical engineering at Gratz. He is inventor of the "Engerth system" for freight locomotives, which, since its introduction on the Semmering Railroad, has found wide adoption on the Continent. The river gate near Nussdorf, which prevents the entrance of ice into the Danube Canal at Vienna and the resultant annual inundations, was devised and built by Engerth. He was architect of the buildings of the Vienna Exposition of 1873, and the entire engineering department was on that occasion placed under his control.

ENGHIEN, ɛn'gyɛn', LOUIS ANTOINE HENRI DE BOURBON, DUC D' (1772-1804). A member of the Bourbon family, celebrated in history for his tragic fate. He was the only son of Prince Louis Henri Joseph de Bourbon and the grandson of the Prince of Condé and was born at Chantilly, Aug. 2, 1772. In 1789 he left France and traveled through several countries of Europe. In 1792 he entered the corps of *émigrés* (q.v.) assembled by his grandfather, the Prince of Condé, on the Rhine. After the Peace of Lunéville in 1801 he went to reside at Ettenheim, an old castle on the German side of the Rhine, not far from Strassburg and within the territories of the Duke of Baden. Here he married the Princess Charlotte of Rohan-Rochefort and lived as a private citizen. When the conspiracy headed by Cadoudal and Pichegru against the life of Bonaparte was discovered at Paris (1804), the police were led to believe that the Duc d'Enghien was privy to it, and the evidence seemed at first to justify their belief. The unfortunate error of a spy further tended to confirm the strong suspicions of Bonaparte, and he resolved to seize the person of the unfortunate Prince and make of him a terrible example for future conspirators. On the night of March 15, 1804, the neutral territory of Baden was invaded, and the Duke captured and carried a prisoner to Vincennes. On March 20 he was tried before a court-martial consisting of eight officers and after a brief examination was condemned to death. Although the evidence had established his innocence, Napoleon had determined that he should die. The grave of the victim had been prepared in expectation of this sentence, and at three o'clock on the morning of March 21 he was shot. His innocence was soon established beyond doubt, and the execution of the Duc d'Enghien has fixed a deep and lasting stigma on the character of Napoleon. The diplomatic effect of the execution was further unfavorable to Napoleon. The Czar of Russia sent an indignant protest to Paris, to which the First Consul responded that the internal affairs of each country were its own concern. A complete rupture of diplomatic relations followed. The reluctance of the Pope to officiate at Napoleon's coronation soon afterward was due in great measure to the horror excited by the unjustified execution of the Duc d'Enghien. Consult: Dupin, *Pièces judiciaires*

(Paris, 1823); id., *Mémoires historiques sur la catastrophe du duc d'Enghien* (ib., 1834); Constant, *Le duc d'Enghien* (ib., 1869); Welschinger, *L'Europe et l'exécution du duc d'Enghien* (Amiens, 1890); Nongarède de Fayet, *Recherches historiques* (2 vols., Paris, 1844); *Correspondance du duc d'Enghien, 1801-04* (ib., 1904); Comte Bonlay de la Meurthe, *Les dernières Années du duc d'Enghien* (ib., 1886); Ropes, *The First Napoleon* (Boston, 1885); Fay, "The Execution of the Duc d'Enghien," in *American Historical Review* (New York, 1904).

ENGIDU, en'gi-dōō. A character in the Babylonian Gilgamesh epic, represented as half man, half bull. Aided by his prowess and strength, Gilgamesh slays Khumbaba, the Elamite, who has usurped the throne of Erech. But Gilgamesh has scorned the love of the goddess Ishtar, who in revenge inflicts upon him a disease and puts Engidu to death. Ea grants the desire of Gilgamesh to see his friend Engidu once more and causes Nergal to let Engidu's ghost rise "like vapor from the earth and make known to his brother Gilgamesh the law of the earth." See GILGAMESH, and consult Ungnad, *Das Gilgameschepos* (Tübingen, 1911), and Jastrow, *Hebrew and Babylonian Traditions* (New York, 1914).

ENGINE. See STEAM ENGINE; INTERNAL-COMBUSTION ENGINE.

ENGINEER, MILITARY. See ENGINEERS, CORPS OF; ENGINEERING, MILITARY.

ENGINEER, NAVAL. In the United States navy the care and operation of all machinery are assigned to line (or executive) officers. The first step towards the organization of a corps of engineers was taken by the appointment of Mr. C. H. Haswell (q.v.) as chief engineer of the *Fulton*. His appointment bore date of July 2, 1836. For some years afterward engineer officers were appointed by the commanding officer of a ship and could be dismissed at his pleasure. But in 1842 Congress passed an Act by which chief engineers were commissioned as officers of the regular navy and the assistants were made warrant officers. In 1845 a supplementary Act transferred the appointing power to the President, as in the case of other officers. The number of engineers increased with the development of steam engines, reaching 2277 in January 1865—1803 volunteers and 474 regulars. The Bureau of Steam Engineering (see STEAM ENGINEERING, BUREAU OF) in the Navy Department was established by the Act of July 5, 1862.

In 1863 the officers of the Engineer Corps petitioned Congress to establish a course of instruction for cadet engineers at the Naval Academy, and this was provided in the Act of July 4, 1864. Several officers graduated; but after a short time the instruction was dropped until 1871, when a regular course of two years was established. This was changed to four years in 1874. The Act of Aug. 5, 1882, amalgamated the cadet midshipmen and cadet engineers under the title of naval cadets. From that time until the Act of March 3, 1899, naval cadets were divided into line and engineer branches at the end of three years, pursuing the higher special studies of their respective branches chiefly in the last year. The Act of 1899 consolidated the engineer corps with the line. The older officers were required to perform engineering duty only, the younger ones to qualify in both branches. The same Act

established the grade of *warrant machinists* (name since changed to *machinists*). Machinists (q.v.) perform watch standing duty on smaller ships and act as junior assistants on the larger ones.

Officers desiring to specialize in engineering are given an advanced course at the Engineer Postgraduate School at Annapolis or at some university. All line officers are required to perform engineering duty and to be competent to stand a watch or act as senior engineer of a ship. But only those who have had more than average experience as assistants are ordered as senior engineers. In the future it is expected that senior engineer officers and designing engineers will be selected chiefly from officers who have taken the postgraduate course in marine engineering.

The amalgamation of the Engineer Corps and the line, though much criticized and for a short time operating with some difficulty, is now a pronounced success. The efficiency of the machinery of all kinds in the war vessels of the United States has never been so high as at present. And the knowledge of the conditions in the engine room, fire room, and dynamo room possessed by deck and commanding officers adds much to the certainty and intelligence with which they are able to carry out their duties.

In European navies the necessity of giving deck and commanding officers a competent knowledge of machinery is being more and more appreciated, and several have taken steps in this direction, though none have yet gone so far as the United States.

EN'GINEER' AND EN'GINEERING. Engineering at the present day may be broadly defined as the practical application of science and scientific methods to industry. Historically engineering is one of the oldest of the professions. The military engineer became a necessary aid in warfare when siege was laid to a fortified stronghold and the attacking force had to advance earthworks over and tunnel under ground exposed to the enemy's fire. The direction of these tunnels, in order to reach a desired point, had to be fixed by an engineer. Early work of this sort was a development of the ancient art of land surveying, and down to the present day surveying has been an important part of the engineer's work. The engineer in charge of the earthworks for attack and defense also had doubtless the responsibility for constructing and operating the military engines of that period. Hamlet's lines, "For 'tis the sport to have the engineer hoist with his own petar," indicates the probable significance of the word "engineer" as late as Shakespeare's day.

Engineering, as defined above—the application of scientific methods to industry—may be said to have had its beginning in the field of transportation. The location of canals required the services of engineers who could apply the methods of surveying developed by the military engineer to the running of lines and levels. The term "civil engineer" accordingly was coined to distinguish those engaged in this work from the older branch of the profession engaged in military operations. It was very early perceived, however, that the engineer was destined to become much more than a mere measurer and computer or even a constructor. Thomas Tredgold, the famous English engineer, in the charter of the Institution of Civil En-

gineers, which he founded, defined engineering as "the art of directing the great powers of Nature for the service of Man."

The development of the modern profession of engineering may be said to have begun with the railway era. In 1829 George Stephenson's locomotive, the *Rocket*, attained a speed of 44 miles per hour in the competitive trials on the Liverpool and Manchester Railway. Immediately thereafter the construction of railways was undertaken in all civilized countries. The services of engineers were at once necessary to locate the railway line and the structures along it, and to measure the excavations and embankments in order to pay the contractors for the work performed. Railway building has ever since been an important branch of engineering work.

An excellent illustration of the evolution of the engineer from the mere measurer to the man who applies skilled judgment and experience to the solution of the highest economic and financial problems is furnished by this very work of railway location. A. M. Wellington, in the Introduction to his *Economic Theory of Railway Location*, said: "It would be well if engineering were less generally defined as the art of construction. . . . To define it rudely but not inaptly, it is the art of doing well with one dollar what any bungler can do with two after a fashion." The same idea was expressed more tersely by E. H. McHenry, who said (referring also to railway location): "Engineering is the art of making a dollar earn the most interest."

To comprehend the significance of these definitions, it should be understood that the locating engineer can vary the first cost of a railway within wide limits at the expense of its annual cost for maintenance and operation. Knowing the volume of traffic to be handled, the ruling rate of interest on capital, and the effect of varying rates of grade and curvature on the cost of haulage, it can be determined what line will yield to its owners the largest net earnings or, if the road is a government enterprise, what line will give the lowest cost per ton of freight and per passenger handled. These and similar problems are solved by the engineer, not as a mere matter of mathematics, but as a matter requiring the exercise of the most careful judgment and a forecast of the future as well.

That the skilled engineer is able successfully to forecast the future in the solution of his problem is admirably illustrated by the Panama Canal work. Perhaps the largest engineering problem ever presented in point of expenditure involved was the question whether that canal should be built with locks or at sea level. In comparing the two plans one essential element was their relative cost. The United States Isthmian Canal Commission of 1899, which recommended the Panama route for adoption, estimated that the cost of digging the great Culebra Cut on the line of the canal, containing nearly 100,000,000 cubic yards of rock, the largest piece of excavation ever undertaken, would be 80 cents per cubic yard. The actual cost to the government up to Jan. 1, 1914, when the cut was practically completed, had been 78.18 cents per cubic yard.

While the term "civil engineering," as noted above, was originally used to distinguish the engineer surveyor who located such public works as railways and canals from the engineer who

applied similar methods to military works, that significance has long been obsolete. Civil engineering at the present day relates to works in connection with transportation, such as railways, canals, and roads, to works which have to do with water, such as public water supply, irrigation, drainage, and sewerage, to works of river and harbor improvement, and to structural works, such as bridges, buildings, dams, piers, docks, etc. In all these fields of work the adoption of scientific methods of design, construction, and operation in place of the methods of the craftsman or guild worker marks the advent of the engineer.

The development of mechanical engineering, which has occurred almost wholly during the past 40 years and chiefly during the present century, means that the art of machinery design and construction has passed from the millwright and machinist to the engineer. Mining engineering is another one of the grand divisions of the profession, including all the work in connection with the exploration for, and the development and mining of, ores, coal, and minerals; while electrical engineering deals with the design, construction, and application of all classes of electrical machinery and apparatus.

Each of these four principal divisions of the profession includes a large and rapidly increasing number of specialties. Mechanical engineering, e.g., includes such specialties as heating and ventilating engineering, automobile engineering, steam engineering, gas engineering, etc. Civil engineering includes structural engineering, sanitary engineering, hydraulic engineering, railway engineering, etc. It would be easy to make a list of 100 or more different specialties in engineering work which are well recognized. The list is constantly increasing as new industries arise and the technology of their processes becomes systematized.

On the other hand, there are many engineers of high standing who do not specialize at all, but act as technical executives and employ and direct the work of civil, mining, mechanical, and electrical engineers to carry to success a great work of construction or conduct a huge manufacturing or mining industry. It is also true that there are no hard and fast lines between even the great divisions of the profession. Many civil engineers have at times done important work in mechanical engineering, e.g., and engineers are constantly changing from one specialty to another as circumstances make necessary. Such transfers are facilitated by the fact that all engineering is based, broadly speaking, on mathematics, physics, and chemistry. Other sciences are also made use of in some branches, such as geology in the work of the mining engineer and botany by the agricultural engineer.

In schools of engineering the courses of study prescribed in civil, mechanical, or other branches of engineering are generally the same for the first two years at least, and many leading educators favor a single four-year course of study for all engineering students, leaving specialization to a postgraduate course or to practical experience. (See TECHNICAL EDUCATION.)

The question as to the number of persons engaged in engineering work cannot be answered by any census statistics. The name "engineer" is applied in the United States, not only to those practicing the engineering profession, but to those operating steam and other engines,

such as locomotive engineers and stationary engineers. In England both the firms operating machine shops and their employees working at the machinists' trade are called engineers. In the engineering profession itself there is no authoritative definition as to what constitutes an engineer. There is no legal restriction upon the practice of engineering in the United States; and while in recent years there has been agitation for such legislation, a large proportion of the profession opposes it.

The best idea as to the probable number of professional engineers in the United States is obtained from the statistics of the engineering societies. The four great American societies of civil, mechanical, mining, and electrical engineers now have a total membership in the United States of 25,000. Admission to these societies is generally conditional upon the attainment of a fair degree of professional standing and experience. Hence the number of men engaged in professional engineering work in subordinate capacities such as draftsmen, instrument men, inspectors, etc., must be several times as great as the membership of these societies. Besides these great national societies, there are between 200 and 300 other societies of engineers, many of local character including the engineers of a city or State, and others devoted to some special branch of engineering work.

The reaction in college education from the classical and literary studies towards the study of applied science has been partially responsible for the enormous increase in the number of engineers in the past quarter century and for the overcrowding of the profession which now exists, notwithstanding the many new fields which have been opened to the engineer in that time.

Besides the graduates from the engineering colleges, the lower ranks of the profession are constantly recruited by men who have gained their engineering knowledge by practical experience, supplemented often by home study with the aid of a correspondence school. Since good judgment based on practical knowledge is the most important requisite to an engineer, those who enter the profession in this way often attain a good degree of success, although they necessarily labor under a handicap compared with engineers who have made the most of their opportunities for study at a first-class engineering school.

The consolidation of industries has had a marked effect on engineering work, and the present tendency is for such work to gravitate into the hands of strong engineering firms, employing on a salary a staff of engineers numbered perhaps by hundreds. Probably at least 5 per cent of the engineers of the United States work at a salary, either for some engineering or manufacturing firm or in city, State, or Federal service. The engineers who carry on private practice are commonly termed consulting engineers, although in nearly all cases they engage in design and construction as well as in the work of investigation and advice properly termed consulting.

The increasing complexity of industry makes the engineer expert more and more a necessary factor, not only in carrying on industrial processes, but in the governmental supervision of industry now so rapidly extending. The New York Public Utilities Commissions have a staff

of engineers numbered by hundreds. The Interstate Commerce Commission requires many hundred engineers in the task of valuing the railways of the country which it has undertaken. Engineers have been chosen as the executive heads of many great railway and industrial corporations, and in nearly every instance an engineer has been selected to fill the new position of city manager in the cities which have adopted that form of municipal government. It is generally recognized by the profession that the advancement of its leading members to high positions of responsibility is due, not only to the ability and experience of the men so promoted, but to the high character that the profession as a whole bears for fidelity to the trusts imposed upon it. The profession is therefore laying greater stress than ever upon the observance of proper ethical conduct by its members.

ENGINEER CORPS, *kör*, UNITED STATES NAVY. See **ENGINEER**, NAVAL.

ENGINEERING, MILITARY. Military engineering in its broader sense is the application of engineering to military purposes. The term was thus used originally to distinguish it from civil engineering. In recent years there has been such marked advance in certain branches of civil engineering (see **ENGINEER AND ENGINEERING**) as to entitle them to the rank of separate professions; as, e.g., surveying, sanitary engineering, mechanical engineering, and electrical engineering. The mechanical military engineering connected with the development of guns and carriages has been gradually developed into the art and science of ordnance (q.v.). Military signaling is now carried on in several armies either by signal corps or by detachments of engineer corps having practically no other duties to perform. (See **SIGNALING AND TELEGRAPHING, MILITARY**.) On the other hand, many of the problems presented to the military engineer are of such nature that they are solved by direct applications of sanitary engineering, mechanical engineering, surveying, general civil engineering, electrical engineering, and architecture, with only slight modifications caused by the military conditions imposed on them. Such, e.g., are topographical surveys preliminary to the designing and construction of permanent fortifications, barracks, and other buildings for the service of troops in time of peace, and water supply and drainage of military posts. In its more restricted sense, therefore, military engineering is now taken to include, on the one hand, those applications of the various branches of engineering to military purposes where the military conditions are paramount, and, on the other, to those operations connected with the movements of an army in all that pertains to attack and defense, and to the design, location, and construction of permanent works of land and seacoast defense more commonly known as fortifications. The subject is generally considered as being divided into, first, military field engineering; second, permanent land and seacoast defense. The present article will deal chiefly with certain features of field engineering, while reference will be made to separate articles which discuss the other important field duties of the military engineer. The subject of land and seacoast defenses is treated under the title **FORTIFICATION**.

Military Field Engineering comprises primarily those applications of engineering to the problems of an army in the field, where the prime

elements to be considered are the amount of time available, the nature of the labor, and the material at hand. From the nature of the movements of large bodies of troops, it is impracticable to carry much material in addition to what is required for the maintenance of the army on the simplest basis. Field engineering, therefore, to be successful must rely largely on the resourcefulness of its representatives. The military engineer who can secure a result sufficiently good to answer the purpose in the time allowed will be more successful in the field than one of greater attainments whose temperament prevents him from taking short cuts and from being satisfied with any work short of perfection. Under the head of military field engineering the following divisions of the subject may be made: field measurements, clearing of land, encampments, military surveys and maps, communications, field fortification, siege works, and military mining.

Of the topics included in this division of the subject, field measurement, clearing of ground, military surveys, topographical reconnaissance and maps, being more or less closely related, will be described in the present article, while separate articles to which the reader is referred will treat the subjects of ENCAMPMENT; ROADS AND RAILROADS, MILITARY; BRIDGES AND DOCKS, MILITARY; DEMOLITION; MINES AND MINING, MILITARY; SIEGE WORKS; FORTIFICATION.

Field Measurements. The rapid approximate measurement of distances is frequently necessary in field operations. For short distances resort is had to the use of the rule and tape. For longer distances, where both extreme points are accessible, measurement is ordinarily made by pacing, running over the line with a wheel, or by estimation with the eye. With practice many officers become extremely expert in the determination of distances by the eye. Where the distance to some inaccessible point, as, e.g., a tree on the opposite bank of a river, is required more accurately than would probably be given by simple estimation, a method

FIG. 1.

in the line BC , as D , lay off a line at right angles to BC . Mark the point E where the line of sight from O to O crosses DE . Then, by similar triangles, having measured DE , DC , and CB , we shall have $BO : BC :: DE : DC$. Therefore,

$$BO = \frac{BC \times DE}{DC}.$$

By a similar but slightly more complicated process, the height of a distant inaccessible point can be determined. Other simple and practical methods for measuring similar distances are described in the field-engineering manuals. A simple way of laying out a right angle in the field is as follows: To lay out a right angle to the line AD at the point A , measure the distance AD equal to four convenient units, as feet or yards; then

FIG. 2.

taking one end of a tape held at D and the other at A , tighten the tape so that the distance XD shall be equal to 5 units and XA to 3. The angle XAD will be a right angle. By bisecting this angle one of 45° can be obtained; by trisecting the latter, one of 15° , etc. To lay off an angle of 60° proceed as follows: At the point E on the line AEB , hold one end of a tape, and with any length, as EB , describe the arc of a circle, as indicated in the cut; with the other end at B and the same radius describe a second arc intersecting the first. From the point of intersection D draw the line DE ; the angle DEB will then be 60° . By bisecting this angle one of 30° can be obtained; by bisecting this, one of 15° ; etc.

FIG. 3.

Clearing of Ground. Various reasons frequently render necessary the clearing of ground in the field. In the case of a position definitely taken up with a view to battle, it is eminently desirable that as much of the ground to the front as lies within rifle range should be cleared so thoroughly that an enemy cannot take advantage of the cover afforded by the brush and trees in advancing on the position. Sometimes it is impracticable to secure sufficient ground for the encampment of the troops without clearing. For cutting away brush the best tools are heavy knives, machetes, billhooks, and brush hooks.

FIG. 4. BRUSH HOOK.

The removal of saplings and trees is usually done with hatchets, axes, and saws where sufficient time and tools are available. Where the urgency is greater, trees may be felled by means of charges of gun cotton or by boring holes in the trees or by placing dynamite against the outside. The amount of clearing that can be done by a man in an hour varies considerably but may be placed usually at from 10 to 25 square yards.

Military Surveys, Topographical Reconnoissances, and Maps. Where a regular survey of a tract of land is desired for some military purpose, such as the construction of a fortification, or a map of a military reservation, the survey will be made in the same manner and under the same limitations as to time expended, accuracy required, and instruments used, as a similar survey for any civil purpose. With the steady extension of the mapping of the world's surface, more accurate maps suitable for use in military operations are becoming available. (See SURVEYING.) Where, however, a special survey is desired for use in connection with the movements of troops or with the planning of a battle, it is almost invariably found to be necessary to resort to hastier methods. These must depend upon the nature of the information desired and the time allowed. Much assistance can frequently be derived from

existing maps of the territory to be traversed. These generally fall short of giving all the information desired, and when they are available must usually be supplemented by topographical reconnaissances. The latter can be made either on foot or on horseback. Some progress has also been effected in late years in reconnaissance by air craft. In general, the information to be obtained is plotted as it is noted, with a view to having the map as nearly finished as may be when the route to be mapped has been traversed. The essentials for such a survey are paper for the map, an instrument for measuring distances, and an instrument for determining elevations and slopes. For many years such maps were, in the first place, plotted directly in notebooks or on pieces of paper ruled in one direction and attached to a light drawing board of such size that it could be readily carried by the reconnoitrer. The bearings of roads and objects were taken by a prismatic compass, or by a pocket compass, and were plotted on the map with the aid of a small protractor. Distances are usually measured by counting the number of steps or strides. Where a wheel of any kind accompanies the reconnoitrer, distances can be determined with reasonable accuracy by noting the number of rotations of the wheel by an odometer or other means. Differences in elevation of points are determined either by a hand level or by computation from the slopes which are measured with a hand clinometer. Many little devices assist greatly in the rapid completion and easy understanding of such a map. For example, if at the end of the day's work a red pencil be run over the roads, a blue one over the rivers and other water surfaces, and a green over the forests, much will have been done to add to the clearness of the map.

It was by these means that many of the topographical reconnaissances of the Civil War were made. The principal inconveniences of the method related to the size of the drawing board and to the fact that provision must be made for carrying the various auxiliary instruments in convenient places about the person. In recent years attempt has been made to develop a sketching case which shall combine all the essential tools for a topographical reconnaissance. One type is shown in the accompanying cut. It has been made possible in this case to use a much

FIG. 5. A MODERN MILITARY SKETCHING CASE.

smaller drawing board because the paper can be rolled back and forth over it by means of the rollers on two opposite sides. The protractor can likewise be moved from side to side in a transverse direction. These two motions permit any point of the paper to be brought under the centre of the protractor. The protractor can be revolved freely around its centre, permitting a line to be drawn in any direction through any point on the paper. The compass

in one side of the board permits the board to be oriented, i.e., placed in a position parallel to the one which it occupied in starting the survey. Holes are provided at one end of the board for holding pencils. A rough clinometer has been added at the other end. The type of sketching case now most generally used is similar to the above, but considered somewhat stronger and better adapted to rough usage. The scale of maps made in the field is almost always in inches and usually between 1 inch to the mile and 6 inches to the mile. As a rule, road sketches are now made on a scale of 3 inches to a mile, and position and outpost sketches, 6 inches to a mile. The 1-inch map is used for extended operations and 12-inch in siege operations. The scale used should be clearly shown on the map. A north-and-south line, the name of the reconnoitrer, and a clear title should also be plainly indicated.

Where the primary object of the survey is to obtain a road map, the road is gone over by the reconnoitrer and mapped directly on the paper. He indicates the position of the most prominent objects within range of the road, noting the names of places. Collateral information as to distances, water supply, camping grounds, food, fuel, etc., may also be given. Under other conditions, positions favorable for offense and defense are noted. The character of the roads so far as these may affect the movement of troops is recorded. Information relative to location and depths of intersecting watercourses, mountain passes, forests, railroads, tunnels, and bridges, is added. After practice an officer of ordinary aptitude can survey and map in this way nearly as much road as he can traverse at the assumed gait. Thirty miles have been mapped in a single day with sufficient accuracy for the desired purposes.

In case something more than a road map is desired, as, e.g., a map of a possible battlefield, more topographic detail should be shown. Everything which may have bearing in the case of a battle should be indicated. For example, in addition to all roads suitable for the movement of troops, there should be shown the depth of cuts, position of stone walls, woods, buildings, marshy ground, relative distances of level of hills and hollows, etc. The symbols used to represent topographical and hydrographical figures are designed to be rapidly made and readily understood and to resemble or suggest the actual figures they represent. In the United States a system of conventional signs for the use of all map-making departments of the government has been recently adopted by the United States Geographic Board. The use of numbers for symbols, somewhat along the lines of the decimal system of library classification, has also been considered. Any good engineer or surveyor can learn in a few days so to adapt his methods as to be able to prepare a fair military map. With additional practice his skill and judgment as to what should be added and what omitted in view of the limitations, as to size of map and time for making it, improve greatly. The usual method of indicating distances of level by means of contours, which are lines passing through all points of equal height, is the best for the purpose and should be used where practicable. The vertical interval varies, but for road sketches 20 feet is common and for position and outpost sketches, 10 feet. These maps contain inaccuracies which in an extended survey

may, if not properly compensated, accumulate and become troublesome. Various means are resorted to for coordinating and correlating the maps of adjacent territory made by different officers. During the Civil War the general maps of the Peninsula were compiled almost entirely from reconnoissances on horseback. The railroad was accurately surveyed and served as a basis, while the wagon roads were mapped by different parties whose trails frequently crossed each other. In this way it was practicable so to adjust the errors as to obtain a general map of considerable accuracy. In General Sherman's march to the sea the topographical parties, which were kept a day in advance of the army, were enabled to furnish maps for the guidance of the commanding general and his subordinates throughout the entire march. Considerable progress has been recently made in the methods. Definite systems have been developed under which a number of men map adjacent parallel and connecting crossroads simultaneously, probable errors are compensated and reduced to a minimum, and the combined result made available promptly upon the completion of the fieldwork. Similarly a section of country is systematically and almost automatically subdivided, the different subdivisions simultaneously surveyed, and the results of all field assistants promptly combined. See Plate of TOPOGRAPHICAL MAP in article MAP.

In order that a map may be of the greatest service, it is desirable that a number of copies of it should be prepared and placed in the hands of the commanding general and his subordinates at the earliest moment after the completion of the survey. Several methods are in use for this purpose. One of the simplest is to trace the map on tracing linen; from this, if daylight be available, a number of prints can be made by the ordinary blue-print process. This work can be expedited by making from the tracing several brown " " " " which can in turn be used " " " " there be sufficient apparatus for making prints. If daylight be not available, prints may similarly be made by artificial light on bromide paper. Map duplication has also been effected with the aid of photography. A negative of the original map, usually on a smaller scale, is made with a camera. This negative is then used for printing positives by any of the usual photographic processes. For further detailed information on this subject, consult: articles in *Report on Proceedings of International Congress of Engineers, Division of Military Engineering* (Chicago, 1893); War Department, *Conventional Signs United States Army Maps* (Washington, 1912); *Professional Papers of the Corps of Engineers, United States Army; Engineer Field Manual* (United States War Department); Call and Stuart, *Individual and Combined Military Sketching* (Leavenworth, 1907).

ENGINEERING INSTRUMENTS. See SURVEYING INSTRUMENTS.

ENGINEERING SCHOOLS. See TECHNICAL EDUCATION.

ENGINEERS, CORPS OF. The Corps of Engineers of the United States army, organized in 1802, originally consisted of one colonel, one lieutenant colonel, two majors, four captains, four first and second lieutenants, and cadets; the whole number not to exceed 20. They were stationed at West Point, N. Y., and formed the nucleus of the present military academy. In

1838 the corps was increased to 47 officers, and a corps of topographical engineers organized and added to it. Sappers, miners, and pontoniers were added in 1846. At the commencement of the Civil War in 1861 three additional companies were provided for, and also one of topographical engineers, which in 1863 was disbanded, and its officers posted to the Corps of Engineers.

In 1866 the battalion of engineers was formed from the companies already organized. In 1901 the authorized establishment was increased to three battalions of four companies each, the company consisting of 164 enlisted men, rank and file, with two additional staff noncommissioned officers to each battalion. The band (28 men) is also included in the total authorized strength of the corps, which, excluding officers, is 2002 men. Most of these troops are now stationed at Washington Barracks, D. C. In 1914 there were companies or detachments at Vera Cruz, Mexico, Vancouver Barracks, Wash., Fort Shafter, Hawaii, Corregidor, Philippine Islands, and West Point, N. Y. During the war with Spain the engineer force was supplemented by three regiments of volunteer engineers.

The *United States Engineer School*, for many years at Willets Point, had charge of the instruction of officers of the corps, as well as of other arms of the service, in torpedo defense and of the former in engineering. Upon the reorganization of the United States army in 1901 the torpedo defenses were turned over to the artillery corps, together with the post at Willets Point, Fort Totten (q.v.); and the school and garrison were transferred to Washington, D. C. The course of instruction at the school is divided into three departments, (a) military engineering, (b) civil engineering, (c) electrical and mechanical engineering. Practical work and practice are combined with theoretical, in all subjects in which it can be advantageously done, and includes the use of instruments, apparatus, and machines.

An *Army Field Engineer School* has also been established at Fort Leavenworth, Kans., in connection with the Army School of the Line. A part only of the engineer officers are sent there. The object of the school is their preparation and that of engineer officers of the organized militia for the better performance of their military duties.

As may be seen from the following statement of its duties, the Engineer Corps is a scientific branch of the military service, and for this reason cadets graduating highest at West Point are usually assigned engineer commissions. The duties comprise reconnoitering and surveying for military purposes, including the laying out of camps; selection of sites and formation of plans and estimates for military defenses; the construction and repair of fortifications and their accessories; the installation of electric-power plants, cables and supplies pertaining to seacoast batteries; planning and superintending of defensive or offensive operations of troops in the field; the construction of fieldworks and fortifications; the creation and demolition of obstacles; the overcoming of such engineering obstacles as the terrain may disclose or the campaign present; examination of routes of communication for supplies and for military movements; construction and repair of military roads and bridges; the construction, operation, and maintenance of military railways when extensive

military operations of a field force are dependent on lines of railway for its supply in advance of the base; the execution of river and harbor improvements; and such other duties as the President or Congress may order. Under this authority the chief engineer and a majority of the members of the Isthmian Canal Commission were selected from the corps of engineers for the construction of the Panama Canal. The field service regulations provide that there shall be attached to each division of an army a pioneer battalion and an engineer field train, including all vehicles, animals, and personnel for transporting heavy intrenching tools, explosives, sand bags, and other engineer equipment and material. They also contemplate that there shall in addition be attached to each field army a pontoon battalion and train. The rank and file of the United States Engineer Corps are not required to be trained artificers before enlistment, instruction being given afterward. They are combatants and receive military as well as technical training. They are divided into non-commissioned officers, privates of the first class, and privates of the second class. During the Civil War many of the engineer officers attained high rank as general officers. Among the more notable names are those of Meade, McClellan, Humphreys, Wright, McPherson, and Warren in the Union army, and Lee, Johnston, and Beauregard in the Confederate army. See UNITED STATES, *Army*.

European Engineer Corps. The *Corps of Royal Engineers* of the English army was organized in 1763 and has always had its headquarters and training school at Chatham, near the south coast. Its strength in 1913 was 1051 officers, and 8742 noncommissioned officers and enlisted men. The latter are recruited from men who have served an apprenticeship to some trade, preferably machinists, electricians, carpenters, masons, bricklayers, smiths, painters, printers, telegraphists, etc. The corps has always been on a different basis from the other branches (excepting artillery) of the army, even in the days of the purchase system, which never applied to the engineers. First appointment as a commissioned officer is obtained through the Royal Military Academy at Woolwich by open competitive examination. Students are examined and classed and receive commissions in the engineers and artillery according to their standing. Those selected for the engineers are sent to Chatham for two or more years before receiving their active commission. Officers and men receive extra pay in addition to their regular daily pay. The peace establishment comprises 5 field troops, 15 field companies, 3 bridging trains, 15 telegraph companies, 1 balloon school, 1 searchlight company, 3 railway companies, 29 fortress companies, 2 coast companies, 3 survey companies, 10 fortress depot companies, 1 feed depot, and 1 colonial survey section. The corps is stationed throughout the British Empire. The pioneer sergeants of all infantry regiments, artificers by trade, must also be in possession of a Chatham certificate. Officers and noncommissioned officers of cavalry and infantry may also obtain certificates as assistant instructors of field works, if nominated to attend the short course of instruction at Chatham set apart for them.

The *French Engineer Corps* consists of 20 battalions, which are formed into regiments in time of peace for purposes of instruction. In

time of war the company becomes the unit. The ordinary company assigned to a division comprises 310 officers and enlisted men. In addition pontoon companies and park companies are assigned to corps and army headquarters. Three of the battalions are made up of special railway companies. European military critics generally give the corps a high rating for efficiency.

The *German Pioneer troops* (*Technische Truppen*) number 29 battalions. The normal battalion has 25 officers and 600 enlisted men in time of peace. In time of war the number of enlisted men is increased from 150 to 270 per company. In time of peace an experimental company is organized in each battalion for testing out new apparatus and consists of 5 officers and 114 men, 95 of whom are detailed from the battalions. There is also a special body of railroad troops, including 183 officers and 4496 men, organized both for building and operating purposes. At the outbreak of war each battalion mobilizes a supply battalion which remains at the home depot to receive and forward men, equipment, implements, and supplies.

The *Russian Engineer Corps* comprises 119 sapper companies, 19 pontoon companies, 77 railway companies, 16 balloon companies, and 46 telegraph companies. The organization of the Russian army calls for the assignment of an engineer battalion to each army corps. The engineer services of *Austria, Italy, Rumania, Holland, Belgium, and Spain* are generally similar in organization to the French and German. As a rule, the European engineers perform the duties assigned in the United States to both the engineer and the signal troops. See ARMY ORGANIZATION; ENGINEERING, MILITARY.

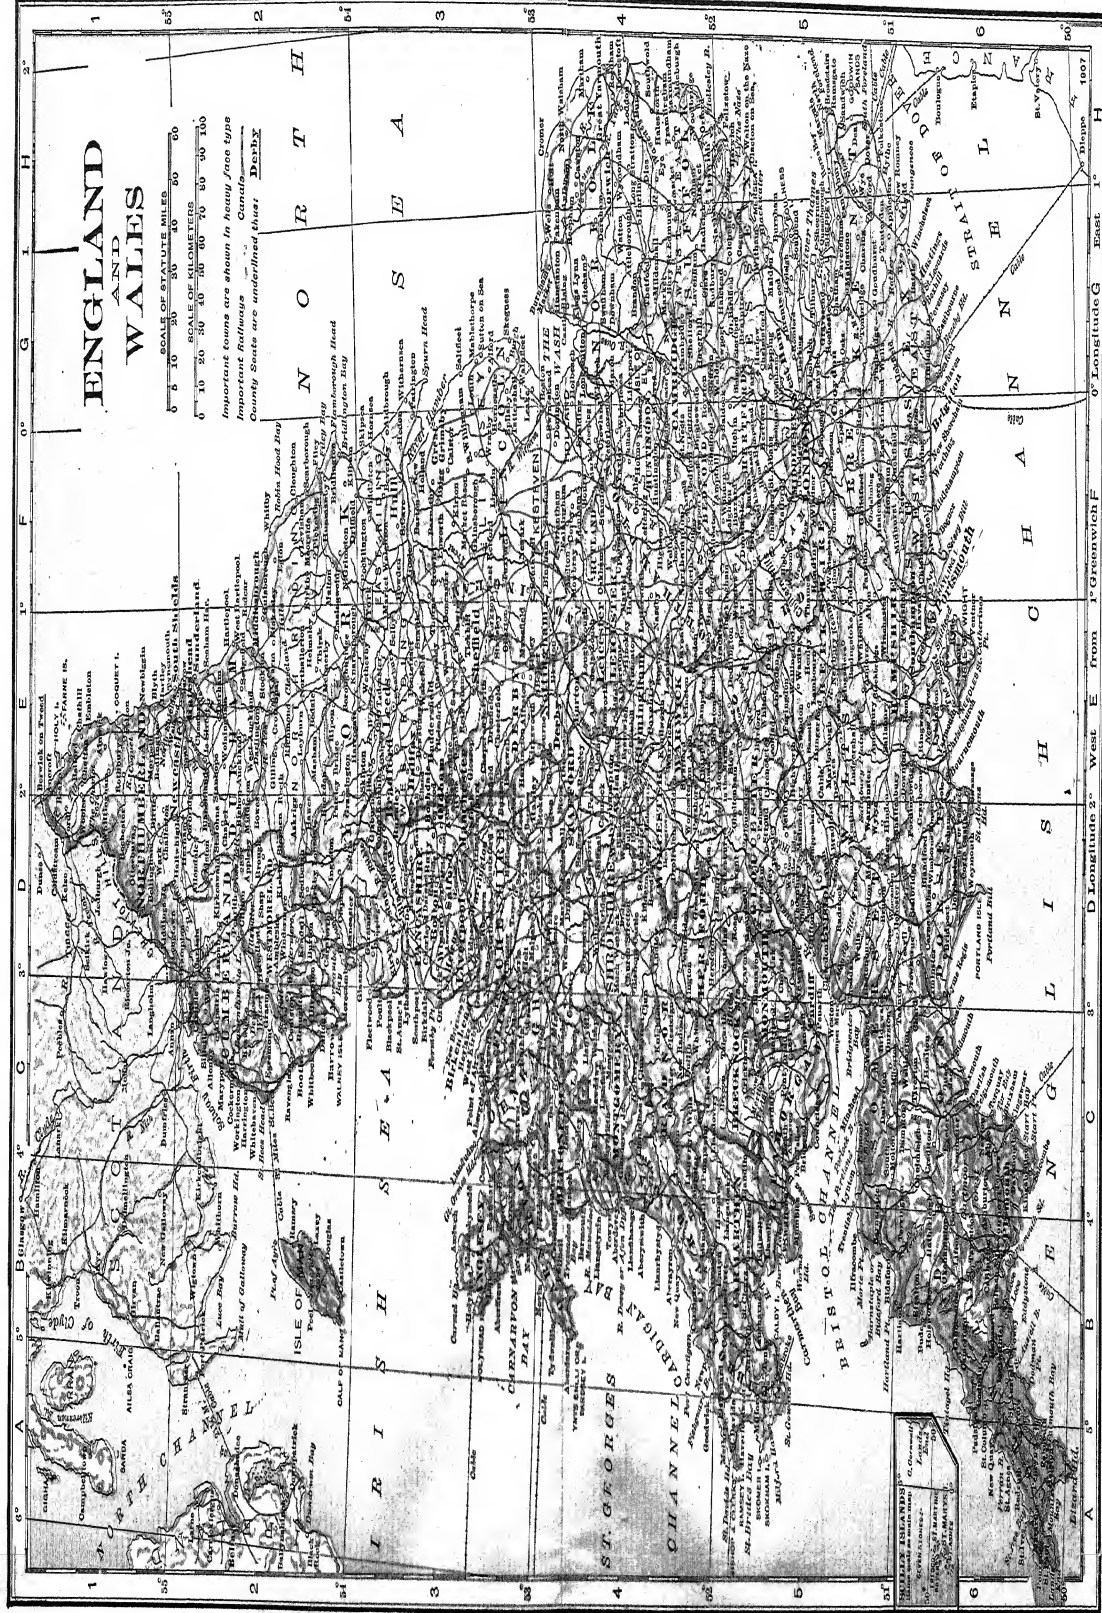

ENGIS, ä'n'zhé'. An archaeological station on the banks of the Meuse, near Liège, Belgium, noted for the discovery of human remains in deposits belonging to the Quaternary period. See MAN, ANCIENT TYPES.

ENGLAND, In'gländ. The most important member of the United Kingdom of Great Britain and Ireland (Map: Europe, C 3). The name England is commonly applied to the entire southern portion of the island of Great Britain, but it will be limited here to the ancient historical division, reserving Wales for treatment under a special head. A general discussion of the physical and climatic features, flora, fauna, etc., of England, as well as of Scotland and Wales, will be found under the title GREAT BRITAIN.

The southernmost point of England is in lat. 49° 57' N., and its northern extremity in lat. 55° 46'. England is roughly triangular in shape and comprises an area, according to official determinations, of 50,851 square miles. The south side of the triangle has a length of 315 miles, while the east and west coasts, about 350 miles and 400 miles long respectively, exclusive of windings, converge northward, the boundary with Scotland being at Solway Firth, the Cheviot Hills, and the river Tweed. The coast is so broken by headlands, bays, and inlets that England alone has a coast line nearly 2000 miles in length, and the localities farthest inland are not more than 75 miles from the sea. All important manufacturing centres are within 50 miles of a seaport. The commercial situation is further improved by numerous navigable rivers, which penetrate deeply into the interior.

Important towns are shown in heavy face type
Important Railways *Canals*
County Seats are underlined, thus: Derby

The greater number of rivers flow to the east, the more important of these being the Thames, Humber, and Tyne. They are longer than the western rivers, which include the Severn and the Wye, are less liable to floods, and are more useful for navigation. Topographically England differs from Scotland and Wales in that a large part of its area is low land. With the exception of the peninsula of Cornwall and Devon, the Lake District, and the Pennine Chain, the country is a coastal plain, broken by minor escarpments and gentle downs, but nowhere exhibiting true mountainous forms, sloping down gradually to the southeast; none of the elevations present formidable obstacles to communication. The geological structure of England is characterized by a variety such as is usually found only in countries of much greater area. In the western highlands the basal formations comprise Archæan gneisses and granites and early Paleozoic sediments, while eastward there is a succession of strata in ascending order up to the Quaternary. The Carboniferous rocks are limited to small areas, but they include numerous coal seams of almost unparalleled thickness. Nearly all of the formations yield minerals of economic value, ranging from gold, silver, and tin to the more common metals and non-metallic products.

Mining. England has great resources of coal, and annually produces about 70 per cent of the coal output of the United Kingdom. There are two principal producing areas—the region about Newcastle and that of southeastern Lancashire, southwestern Yorkshire, northern Derbyshire, and western The production of the former was: Durham, 41,719,000 tons; Northumberland, 14,683,000; and of the latter district, Yorkshire, 39,137,000; Lancashire, 23,675,000; Derbyshire, 17,171,000; Nottinghamshire, 11,623,000 tons. Other producing regions in 1911 yielded amounts as follows: Staffordshire, 14,050,000 tons; Monmouthshire, 13,799,000, and other districts, 14,388,000 tons; total, 190,244,000 tons, as compared with 271,892,000 for the United Kingdom. Wales produced 39,845,000 tons. There is usually a slight annual increase in production, and increasing amounts are annually shipped to foreign countries. England is the greatest coal-exporting nation, because its mines are nearer to seaports than those of any other great producing country, and the largest coal buyers are the neighboring countries of Europe. The total coal production of England and Wales in 1911 was 272,000,000 tons, valued at approximately \$550,000,000. The exports of coal and coke in 1911 amounted to 67,000,000 tons valued at nearly \$200,000,000.

England produces scarcely any of the precious metals, and of the others, iron is the only one that is produced in large quantities. The annual output of iron is exceeded only by the United States and Germany, though the home demand is so great that the local production supplies but about two-thirds of the quantity used in home industries, while the stated value of that imported exceeds the stated value of the home product. A great advantage of the iron industry is that the coal needed to fuse the ore and the limestone required for fluxing are found near the ore. Yorkshire supplies the greater portion, but north Derbyshire and Cumberland supply the valuable red hematite ores, while the black iron ore of Sweden and the hematite

of Spain are largely imported. Tin ore is mined in Devon and Cornwall, the largest European sources of the metal. Copper ore is now nearly exhausted. In Northumberland lead and zinc are mined together.

Fisheries. The greater part of the large annual fish catch of the British Isles is accredited to the English and Welsh coasts, and fish is the only article of food that is yielded in adequate supply. The total value of the product (English and Welsh coasts) increased from £3,683,063 in 1887 to £6,816,375 in 1902 and £9,210,881 in 1912. Great Yarmouth, Grimsby, and Hull are the centres of the industry; but the greater part of the catch goes to Billingsgate, London, which is the largest fish market in the world. The herring catch was valued at £1,665,000 in 1912; cod, £1,448,000; haddock, £1,350,000; plaice, £1,051,000; hake, £598,000; soles, £464,000. A great many fish are brought alive in tanks on the fishing vessels to the ports, whence they are sent on fast trains to the great centres of consumption.

Agriculture. England differs from other countries outside of the United Kingdom in the remarkable extent to which her lands are concentrated in the hands of a small percentage of the population and in the universality of the capitalistic system of tenure. It is estimated that all estates exceeding 125 acres in area, amounting to four-fifths of the total cultivated area, are held by 38,000 landlords. The greater part of the agricultural land is rented. In 1911 the acreage under crops and grass occupied by owners was 2,970,632 in England, 276,339 in Wales, and 569,881 in Scotland, while the total cultivated area in Great Britain was 32,094,658. The number of farm holdings was 374,653 in England and 60,657 in Wales; those from 1 to 5 acres numbered 82,538 in England and 10,210 in Wales; 5 to 50 acres, 167,628 and 32,112; 50 to 300 acres, 110,110 and 17,965; over 300 acres, 14,377 and 370; total, 374,653 and 60,657. Average size of holdings, 65.3 acres in England and 45.7 in Wales. Of the total number of holdings in England, 326,529 (or about 87 per cent) were rented; in Wales, 54,605 (90 per cent). As compared with the United States, the system of cultivation is more intensive, requiring a much greater outlay of capital, which is furnished by capitalist farmers, and hence the method is known as the capitalistic system. More is expended upon each of the items—rent, labor, fertilizers, and machinery—than in the United States, estimated upon an acreage basis. England, more than any other European country, has followed the example of America in the adoption of labor-saving machinery, and this has been partly responsible for the diminution in the number of agricultural laborers. The other factor which tends to lessen the number of agricultural laborers is the recent decrease in the raising of crops. The increasing competition of the United States and other foreign countries that are favored with cheap land and cheap transportation, and that do not yet find it necessary to buy so large an amount of expensive fertilizers, has been disastrous to the interests of the English farmer. The cost of transporting grain from other parts of the world has been greatly reduced, the freight rate on wheat from New York to Liverpool having averaged about 3 cents per bushel from 1900 to 1910 against 21 cents in 1873, 9 cents in 1883, and 5 cents in 1893. The principal crops are

wheat, barley, oats, beans, turnips, potatoes, hay, and fruits. The numerous large towns afford a market for a large gardening industry.

Stock raising is very important. The towns are so numerous that milk is the chief dairy product, no other country depending so largely upon imports of butter. The north and west, or the elevated and more humid portions of England, are largely given over to grazing, while in the eastern portion the growing of cereals and other crops is more common, though stock raising is also prominent throughout this region. The three coast counties—Lincolnshire, Yorkshire, and Essex—lead in the production of wheat, the average yield in these counties sometimes approaching the remarkable figure of 40 bushels per acre. No country surpasses England in the superior quality of her domestic animals, and no other has contributed so many varieties of the standard breeds. The name of the county or region in which the breed originated is generally used to designate them, such as the Devonshire, Lancashire, or Durham cattle, Southdown sheep, and Berkshire hogs. There are 10 or 12 native breeds of cattle, the most important being the Shorthorn, which, originating in the Tees district of Durham over a century ago, has spread all over the country and is widely distributed abroad. Hereford and Sussex cattle are famous for beef, and Shorthorn and Devon for both beef and milk.

Manufactures. England is so richly endowed in manufacturing industries as numerous as the farmers; the percentage thus employed is larger than in any other country. The extensive resources of coal and iron have been the most prominent of the numerous influences which have fostered the development of manufacturing. The textile industry leads in importance, there being, in 1907, 1,087,223 persons employed in the textile factories of England and Wales, of whom 679,863 were females. The proximity of coal fields, commercial advantages, and an atmosphere laden with an unusual amount of moisture, important in spinning, have all favored the centralization of the industry in limited regions in the north of England. Cotton manufacturing, which has long been the chief branch of the textile industry, is centred in the Manchester district, the city of Manchester itself being the commercial centre of the industry. The surrounding towns, however, including Oldham (which possesses one-third of all the cotton spindles in England), Bolton, Blackburn, Preston, Rochdale, Burnley, and Stockport, do most of the spinning, and two of them, Preston and Burnley, most of the weaving.

The woollen industry is centred in the portion of Yorkshire adjacent to the Manchester district, i.e., the West Riding of Yorkshire. Leeds and Bradford are the two most important woollen-manufacturing towns—the one being noted for its broadcloth, the other for alpaca, mohair, and woollen damasks. Huddersfield, Halifax, and Wakefield are also worthy of note for their production of woollens. A number of woollen factories are also located in Gloucestershire. England does not compare with Ireland in the production of linens, though the industry is of some importance in the towns of Leeds and Barnsley. Silk manufacture is of decreasing importance, but is still carried on in Coventry, Macclesfield, and other towns south of the cotton and woollen manufacturing regions.

The localization of metal manufactures and

manufactures of machinery, etc., which rank next in magnitude to the textile industry, is determined largely by the resources of coal and iron, and hence these are the most developed in the northern part of England. Birmingham, the southernmost of the large centres of this industry, is noted for the production of all kinds of metal work, and particularly gun barrels. Sheffield is another town in which manufacturing of iron and steel is the chief industry, steel cutlery being its specialty. Leeds and Manchester produce enormous quantities of machinery, while Newcastle-upon-Tyne and Sunderland lead English towns in shipbuilding. England is a large producer of beer, Burton-upon-Trent leading in its manufacture. The manufacture of pottery and earthenwares is an important industry in north Staffordshire, along the headwaters of the Trent, where china clays abound. A number of places, including the Tyne district and the south of Lancashire, have large manufactures of chemicals.

Transportation. England is exceptionally well provided with transportation facilities. The extensive coast line and navigable waterways afford excellent natural advantages, and these have been supplemented by a remarkable artificial system. Through the canalization of streams, and the construction of a network of canals, almost every part of the country is accommodated with this method of transportation. The importance of the canals has, however, greatly declined, as most of them are too shallow and narrow for the present demands of traffic. The highways are kept in an almost perfect condition. The bulk of the transportation, however, is done by railways. The railway mileage in England and Wales in 1902 was 15,501, and, in 1912, 16,223. The railways now also have control of a considerable part of the canal system. London is the focal point of the principal lines, which include the Great Western, the London and Northwestern, the Midland, the Great Northern, the Great Eastern, and the Southwestern, all under private ownership and management.

Commerce. In various ways England has been greatly favored as a commercial centre and as a carrier of the world's commerce. London is the greatest trade centre in the world and has the largest shipping tonnage, while Cardiff (Wales) and Liverpool are exceeded in shipping tonnage outside of England only by New York, Hamburg, Antwerp, Rotterdam, and Chicago. The shipping of Cardiff is mainly confined to its heavy export of coal; the trade of Liverpool is largely with America and West Africa, consisting of heavy imports of grain, cattle, and other food products and cotton, and exports of manufactured goods and machinery. The trade of London is more widely distributed, but is particularly large with European and Oriental countries, its imports being considerably in excess of its exports. See *Commerce*, under GREAT BRITAIN.

Population. England, with 669 inhabitants to the square mile, is the most densely populated country in the world. The population increased from 11,281,883 in 1821, to 27,483,490 in 1891, to 30,813,043 in 1901, and 34,045,290 in 1911, in the latter year constituting 75.3 per cent of the population of the United Kingdom, as against 74.3 per cent in 1901, 56.1 in 1841, and 54 per cent in 1821. The percentage of increase in the decade ending with 1901 was 12.1,

as against 20.7 for the United States in the decade ending with 1900. From 1901 to 1911 the increase was 10.5 per cent, as compared with 21 per cent in the United States from 1900 to 1910. In common with most of the civilized world, England shows a steady decline in birth rate and death rate. In England and Wales the birth rate decreased from 29.3 per thousand in 1898 to 26.5 in 1907 and 23.8 in 1912; the death rate for these years was 17.5, 15.1, and 13.3. The increase per cent by births, in England and Wales, in the ten-year period 1891-1901 was 31.57; decrease by deaths, 19.18; natural increase, 12.39; in the ten-year period 1901-11, increase by births, 28.56; decrease by deaths, 16.13; natural increase, 12.43. The actual increase per cent in these two periods was 12.17 and 10.89, the difference between natural increase and actual increase being accounted for by excess of emigrants over immigrants.

In 1911 the number of males in England was 16,421,298 and of females 17,623,992 (or 1073 females to 1000 males); in Wales, 1,024,310 males and 1,000,892 females (or 977 females to 1000 males).

England is characterized by its large city population, a larger percentage being urban than in any other country. In England and Wales the population of urban districts in 1901 numbered 25,058,355, and of rural districts 7,469,488; in 1911, 28,162,936 and 7,907,556. In 1851 the percentage of population in urban districts in England and Wales was approximately 50.2; in 1861, 54.6; in 1871, 61.8; in 1881, the actual percentage was 67.9; in 1891, 72.0; in 1901, 77.0; and in 1911, 78.1. The report on the 1911 census points out that the increase in the proportion of the population resident in urban districts, although mainly due to an actual growth of the population within those areas as existing in the earlier census years, is also partly to be accounted for by the extension of those areas themselves, owing to the absorption of areas which were previously rural. Thus, while the 1901 population of urban districts was 25,058,355, the 1901 population of urban districts as constituted in 1911 was 25,351,118 (the 1901 population of rural districts as constituted in 1911 being 7,176,725). The general increase per cent in England and Wales was 10.9 in the period 1901-11; the urban increase was 11.1 and the rural 10.2. In the preceding intercensal period the rates of increase in the urban and rural districts (as constituted in 1901) were 15.2 and 2.9 respectively. Thus, while the rate of increase in urban districts has declined, that in rural districts has risen; it should be pointed out, however, that the rates in the last decennium represent an actual increase of 2,811,818 persons in the urban and of only 730,831 persons in the rural districts.

Below are named the urban districts which in 1911 had upwards of 5000 inhabitants each; the table shows their area in acres, their population in 1901 and in 1911, and the percentage of increase during the decade. In the case of Birmingham, Burnley, Reading, and Sheffield, the boundaries were extended subsequent to the census, and the figures given are for the new areas; but the figures for the areas existing at the time of the census are shown in the line immediately following (c.b., county borough; m.b., municipal borough; u.d., urban district, specifically so called).

TABLE OF URBAN DISTRICTS SHOWING AREA, POPULATION, ETC., FOR DECADE ENDING 1911.

URBAN DISTRICTS	Population			
	Area Acres	1901	1911	Inc. %
London (Adm. Co.)	74,816	4,536,267	4,521,685	-0.3

* The county borough of Stockport is deemed to be situated in the administrative counties of Chester and Lancashire, but the entire borough is here included in Cheshire.

† The county borough of Bristol is deemed to be situated in the administrative counties of Gloucester and Somerset, but the entire borough is here included in Gloucestershire.

‡ The county borough of Great Yarmouth is deemed to be situated in the administrative counties of Norfolk and East Suffolk, but the entire borough is here included in Norfolk.

§ The county borough of York is deemed to be situated in each of the three administrative counties of the East, North, and West Ridings of Yorkshire, but the entire borough is here shown separately.

|| Cambridgeshire is not an administrative county, but its component parts, Cambridge and Isle of Ely, are administrative counties, likewise in the case of Hampshire (with respect to Southampton and Isle of Wight) Lincolnshire (Parts of Holland, Parts of Kesteven, and Parts of Lindsey), Northamptonshire (Northampton and Soke of Peterborough), Suffolk (East Suffolk and West Suffolk), Sussex (East Sussex and West Sussex), and Yorkshire (East Riding, North Riding, and West Riding).

At the 1911 census, among the 1137 urban districts of England and Wales, there were 97 (including the administrative county of London as one district) each of which had a population exceeding 50,000. These districts in 1891 had a population of 13,779,848; in 1901, 15,886,874 (the increase being 15.3 per cent); in 1911, 17,251,009 (increase 8.3 per cent). London (i.e., the administrative county, embracing 74,816 acres) had, in 1911, 4,521,685 inhabitants, as compared with 4,536,267 in 1901, the decrease being 0.3 per cent. The City of London (comprising 675 acres) decreased from 37,702 in 1891 to 26,923 in 1901 and 19,658 in 1911, the decrease per cent in the two intercensal periods being 28.6 and 27.0. "Greater London" is a term used to describe the combined Metropolitan and City of London police districts; it contains, besides the administrative county of London, a wide belt of suburban towns and districts, known as the "outer ring." This outer ring had, in 1891, 1,405,852 inhabitants; in 1901, 2,045,135; in 1911, 2,729,673; the increase per cent in the two intercensal periods being 45.5 and 33.5. The outer ring in 1911 embraced the following areas: in Surrey, 80,099 acres, with 526,366 inhabitants (increase over 1901, 36.8 per cent); in Kent, 43,281 acres, with 172,327 inhabitants (14.1); Middlesex (entire administrative county), 148,701 acres, with 1,126,465 inhabitants (42.1); in Hertfordshire, 36,091 acres, with 54,905 inhabitants (22.7); in Essex, 60,436 acres, with 849,610 inhabitants (26.4); total, 368,608 acres, or 576 square miles, with 2,729,673 inhabitants (33.5). Greater London (i.e., the administrative county plus the outer ring) embraced 443,424 acres, or 693 square miles, with 7,251,358 inhabitants. Greater London in 1861 had 3,222,720 inhabitants; in 1871, 3,885,641 (the increase being 20.6 per cent); in 1881, 4,766,661 (22.7); in 1891, 5,633,806 (18.2); in 1901, 6,581,402 (16.8); the percentage of increase from 1901 to 1911 was 10.2. The percentage of increase from 1861 to 1911 was 125.0, that of the administrative county being 61.0 and that of the outer ring 559.0.

Education. The extension of educational facilities in England, with adequate opportunities for elementary instruction for all, is a recent development. From the first the question of religion has been one of the most influential factors in determining the history of the educational movement. For a long time the efforts of the state in behalf of education were confined almost wholly to grants in aid of denominational or private schools. In districts where ample school accommodations are not provided school boards are elected by the people, women who are independent ratepayers being entitled to vote. By the cumulative system of voting, minority religious sects are able to secure representation on the board. School-attendance committees are appointed in districts where there are no school boards. There is a compulsory act for the attendance of children of 11 years of age and under, and from 12 to 14 there is compulsory attendance, but with provision for conditional exemption. Parliamentary aid is given to poor districts in which the local rates are not adequate. Aid is also given to voluntary (denominational or private) schools in districts not provided with board schools, the grant being upon the basis of average attendance. In the administrative counties, excluding London and the county boroughs, the attendance

at the voluntary schools much exceeds that of the board schools; but in London and the county boroughs the reverse is true. Tuition, since 1891, has been practically free. At the end of the school year 1912, 6,037,370 pupils were enrolled in the public elementary schools of England and Wales; average attendance, 88.79 per cent. Nonsectarian religious instruction is given at the board schools; but such instruction must be either at the beginning or end of the school session, and any child may be withdrawn by his parents from such instruction. At the voluntary schools sectarian instruction may be given. In 1900 the control of elementary education was vested in a Board of Education, this body taking the place of the Education Department and the Department of Science and Art. Illiteracy is rapidly decreasing, as is shown by the decreasing number of persons who sign the marriage registers by mark, these amounting in 1903 to 1.9 per cent of the males and 2.3 per cent of the females.

Secondary education is not well organized. Heavy grants have been made for technical education, but the term "technical instruction" was interpreted to include all secondary education except the dead languages, and thus secondary instruction profited from the grants rather than the purely technical branches. The evening continuation schools mostly cover the field of secondary instruction and have attained a remarkable growth. In 1912, 784,984 pupils were in average attendance at the 8561 evening and similar schools. Much is being done also, both in the field of secondary and of higher education, by university extension work. The question of means and methods for providing better secondary educational facilities is one of the primary points of consideration in the educational controversy which has become so acute in England.

At the beginning of the nineteenth century Oxford and Cambridge were the only English universities. During that century four others were added, of which London University, established in 1836, has a larger faculty and attendance than any other English university. Durham University was established in 1831, Victoria University of Manchester in 1880, Birmingham University in 1900, Liverpool University in 1903, Leeds University in 1904, Sheffield University in 1905, and Bristol University in 1909.

Religion. England has an established state church, commonly called the Church of England. However, there are numerous dissenting churches, and in attendance and membership throughout the country the state church is supposed to lead by a slight majority only. The faith of the church, since the Reformation, is known as Protestant Episcopal; but while the name includes the whole organization, as a matter of fact the church membership is divided into factions whose positions are widely divergent on matters of belief. In recent years the High Church, or Ritualistic faction, which is reactionary in its tendencies, approximating the Roman Catholic church in its extremes, has been most active and aggressive, and has become the dominating element in the church. The Broad Church, representing an opposite or liberal tendency in belief and ritualism, though much smaller in its following, has also increased at the expense of the original Low Church. Another feature that is in a way connected with the recent religious movement within the

state church is the increased rate of growth of the Roman Catholic church, as it is a part of the general tendency to revert to a more definite dogma and a more elaborate ritualism. It is true, however, that the Catholic church has for a long time gained, and still gains, much from immigration, particularly that from Ireland. The number of Roman Catholics in England and Wales was estimated as over 1,800,000 in 1913. There are no governmental religious statistics from which may be made comparative studies of the different denominations; but the figures here used (the estimates include Wales) are taken from reasonably reliable estimates. From these it is found that among dissenting bodies the Methodists are strongly in the lead, the Wesleyan branch, with 516,596 (1910) communicants, far exceeding in numbers any other form of Methodism. The Congregationalists and the Baptists, with 454,810 and 418,680 communicants respectively, are next in numerical strength, while the Presbyterians, who are so predominant in Scotland, number only 86,608. The Salvation Army has a considerable following, and there is a large number of small denominations, including Bible Christians, Friends, Unitarians, etc. Special emphasis is placed upon Sunday-school work, the number of scholars claimed by most of the denominations being more than twice the number of their communicants. Jews are estimated at 196,000.

Ethnology. The racial history of England covers many thousands of years. Chipped stone implements of the Chellean type have been found in the Thames valley, associated with bones of elephants, also at Hoxne in Suffolk, in the valley of the Ouse, in the Isle of Wight, in the valley of the Avon, and in the caves of Brixham, Ken's Hole (Devonshire), of Robin Hood (Derbyshire), and in Wookey Hole (Somersetshire). The middle, or Mousterian, epoch is not fully represented, and fewer still of Magdalenian implements have been found. In 1913 a very old type of skeleton was found in Sussex associated with Chellean implements, indicating that the British Isles have been inhabited from the earliest times. (See MAN, ANCIENT TYPES. Consult Duckworth, *Prehistoric Man*, Cambridge, 1912, for summary of explorations.) The earliest neolithic race known was long-headed (dolichocephalic), so much so that Boyd Dawkins was disposed to identify them with the Eskimo. Then followed the man of the Long Barrows, who buried his dead in stone chambers covered with oval mounds. He was low in stature and also long-headed, and some of his descendants are still to be seen in Devonshire and elsewhere. The Round Barrow man, who followed with the use of pottery and metals and burning his dead, was, on the contrary, above the average in height, strong-jawed, and broad-headed (brachycephalic). Who was this brachycephalic man? Opinion is divided. Doubt has been expressed as to his Celtic origin, and he has even been assigned to the northern Mongolian or Turanian race. At any rate, a primitive dark people of Celtic speech was later overlaid by a lighter one. The dawn of written history witnessed the invasions of Teutonic long-heads and the retiring of the Round Barrow man. The Romans in their conquests changed the biological character of the English but little. Saxon, Dane, Norwegian, and Norman, all long-heads, century after century, pushed the broad-heads into Wales, North Scotland, and Ireland.

The largest proportion of the people of England are now dolichocephalic (index, 76-79). This uniformity in head form proceeds from two ethnic types—the Mediterranean or Iberian in Spain and the Teutonic in Scandinavia. Consult: Keane, *Man: Past and Present* (Cambridge, 1899); Ripley, *Races of Europe* (New York, 1899); Macnamara, *Origin and Character of the British People* (London, 1900); Keith, *Ancient Types of Man* (ib., 1911). In the supplement to the last-named work, under the head "British Isles," will be found an exhaustive list of the many valuable works on the ethnology of England.

HISTORY

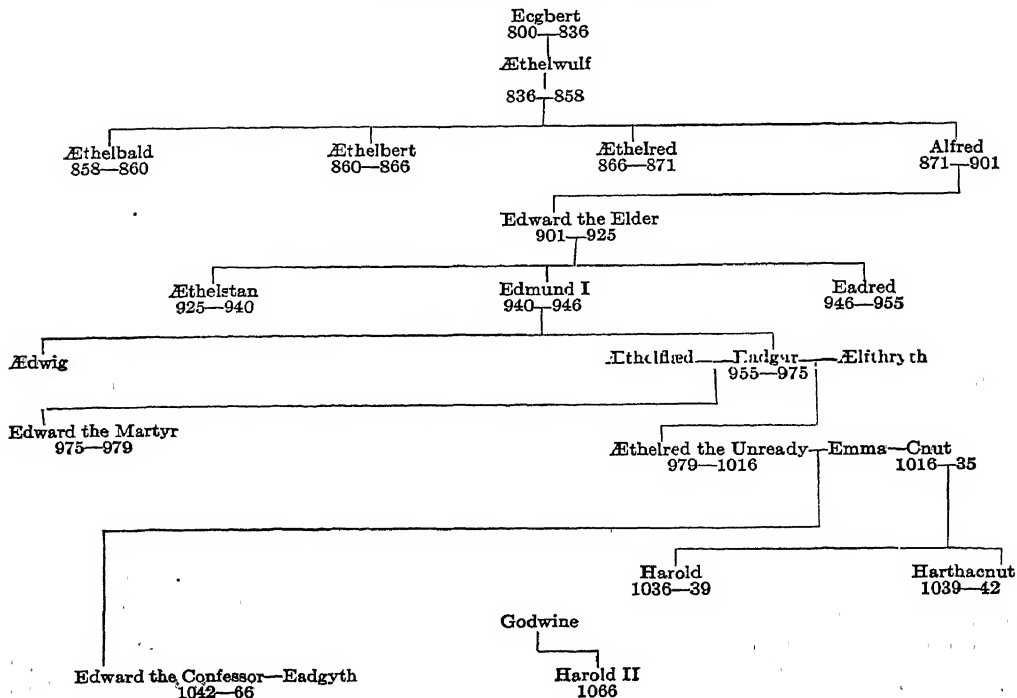

Of the inhabitants of England before the first century B.C. little is known. In some of the ancient geographers there are a few scattered notices of a rude population, with whom a limited commerce in tin was carried on by the Phœnician merchants; but further than this our information scarcely extends. (See *BRITANNICÆ INSULÆ*.) With the two invasions of Julius Cæsar, in 55 and 54 B.C., the recorded history of England may be said to begin. It was not until a century later, however, that the Romans made a serious attempt to conquer the island. Between 43 and 84 A.D. they subdued all that portion of the island south of the Firth of Forth, and after that they held possession for over 300 years. The Christian religion was introduced, and the people became Roman to a very great extent. During the period of migrations the Romans were compelled, early in the fifth century, to recall the legions from Britain. (See *BRITANNIA*.) Consult, for the Roman occupation of Britain, Haverfield, *The Romanization of Roman Britain*, 2d ed. (Oxford, 1912); for

both the Pre-Roman period and Cæsar's invasions of the island, see Holmes, *Ancient Britain and the Invasions of Julius Cæsar* (Oxford, 1907). An account of the country during the period intervening between the withdrawal of the Romans and the Norman Conquest will be found under *ANGLO-SAXONS*.

During the latter half of the reign of Edward the Confessor (1042-66) the government was actually directed by Harold, son of Earl Godwin; and on the death of Edward, Harold, although not of the royal line, was chosen King by the nobles and bishops. William, Duke of Normandy, claimed that this election was illegal and that the crown belonged rightfully to him. He based his claim (1) on his wife's claim through descent from Alfred and on his own kinship to Edward; (2) on an alleged promise of the crown made by Edward; (3) on an oath of support which Harold was said to have given. With the blessing of the Pope and at the head of an army of adventurers, William invaded England in 1066. On October 14 the two rivals engaged in battle at Senlac, near Hastings, and the army of Harold was overthrown and he himself slain. The greater part of the nation was soon weary of the strife, and on Christmas Day, 1066, William received the crown through election by the Witan. During the next five years the conquest was completed, and William was universally recognized. He remodeled the church, replacing the English clergy with Normans and asserting his own supremacy. He checked the power of the nobility by the Salisbury Oath, in 1086, when every free man swore fealty directly to the King; by the abolition of the great earldoms which had existed under Edward; by bestowing many small and scattered fiefs, instead of large contiguous tracts of lands on his

chief tenants; and by maintaining the old local moots, which were independent of the baronial courts. He conciliated the people by his strict justice and by confirmation of the laws of Edward the Confessor. William caused a survey to be made of all the lands in England, the results of which were embodied in the Domesday Book, completed in 1086. His son, William Rufus (1087-1100), ruled tyrannically, and provoked revolts both among the chief barons and the clergy. After his death Henry I (1100-35), his brother, usurped the throne and won general support. He granted the Charter of Liberties (1100), by which the evil customs of the preceding reign were abolished. He married an English wife and showed especial favor to his English subjects, who in return supported him against his brother Robert, Duke of Normandy. He made peace with the church by recalling the Archbishop of Canterbury, who had been exiled by his brother, and by arranging a compromise concerning the subject of investitures (q.v.) on practically the same lines as the Concordat of Worms. (See CONCORDAT.) Unfortunately Henry's son and heir was drowned in the White Ship, in 1120, and this led to a civil war, for Henry persuaded the Great Council to swear allegiance to his daughter Matilda; but after his death his nephew, Stephen of Blois, seized the crown and won the support of London and some other sections. The war between the adherents of Stephen and Matilda dragged on from 1136 to 1153. During this time the nobles became all-powerful, building many "adulterine" (i.e., unauthorized) castles, and the clergy became independent of royal control. In 1138 King David of Scotland, who was supporting Matilda, was defeated in the Battle of the Standard. From 1139 Matilda herself waged war in England. Stephen was generally unsuccessful, and in 1153 he was obliged to conclude the Peace of Wallingford, by which Henry, son of Matilda and of Geoffrey Plantagenet, Count of Anjou, was accepted as Stephen's successor.

With the accession of Henry II (1154-89), the first Plantagenet King, England entered upon a new phase of its history. His possessions in France were far more extensive than in England. From his father he inherited Anjou, Maine, and Touraine; from his mother, Normandy and a claim to the overlordship of Brittany. By his marriage with Eleanor, the divorced wife of Louis VII of France, he had secured Aquitaine. For a time there was danger that England would become merely a province dependent upon the French lands of Henry. There was also a great possibility that Henry might wrest from the French King, whose territories were insignificant in extent by the side of Henry's, the overlordship of all France. Henry spent most of his reign on the Continent, ruling his territories; yet he found time to reestablish the royal authority in England. He maintained order, secured greater power for the royal judges, who made yearly circuits, gave authority to grand juries to examine into criminal cases, enrolled all the freeholders, and compelled them to bear arms in his service by the Assize of Arms. In attempting to reform the church and restrict its authority, by the Constitutions of Clarendon (1164), he came into conflict with Thomas à Becket. (See BECKET, THOMAS À; CLARENDON, CONSTITUTIONS OF.) The murder of Becket compelled Henry to abandon for a time a part of his claims to control the church: but, on the whole,

he was able to assert his authority effectively later in his reign. He also became Overlord of Scotland and Wales, whose rulers submitted to him. In 1171 he invaded Ireland and was recognized as ruler by most of the Irish kings. The real conquest of Ireland (q.v.), however, did not take place for some centuries. Henry's autocratic administration made many rebels. Chief among these were his own sons, who successively rose in insurrection and were aided by the French kings. Two of his sons—Henry, the heir to the throne, and Geoffrey—died during their father's lifetime. Finally, the coalition of Philip Augustus of France and Richard the Lion-Hearted, Henry's third son, who were joined soon after by John Lackland, the King's youngest son, defeated Henry, in 1189. His death followed almost immediately. Richard (1189-99) spent less than a year in all in England. The first half of his reign was spent on his Crusade; the second in an indecisive war with France. At his accession a great massacre of Jews took place at York, greatly to Richard's anger. The excessive taxation necessitated by Richard's foreign expeditions aroused great discontent. His brother John (1199-1216) was extremely tyrannical and cruel. His evil rule caused a general revolt, which resulted to the great advantage of the whole nation. Philip Augustus stripped him, in 1202-03, of a great part of his French possessions, under a decree of confiscation, because John refused to go to the court of his overlord, Philip, to answer crimes charged against him and to do homage for his fiefs. A dispute about the election of an archbishop of Canterbury caused a quarrel between Pope Innocent III and John, who refused to receive Stephen Langton (q.v.), the nominee of the Pope. In 1208 Innocent placed England under an interdict, and the following year excommunicated John. The latter attempted resistance, but when he feared to be deposed by the Pope in 1213, and realized that he could expect no aid from his disaffected subjects, he submitted and became the vassal of the Pope, accepting England as a papal fief and agreeing to pay 1000 marks each year in recognition of his vassalage. He had felt obliged to surrender to Innocent because he was threatened with a revolt of his own subjects, and hoped to break their resistance by the Pope's aid. When, however, his attempt to reconquer his French territories was defeated by the victory of Philip Augustus over Otho IV of Germany, the ally of John, at Bouvines (1214), his subjects determined to revolt. The barons met in January, 1215, and demanded the redress of their grievances. As John procrastinated, they marched in arms against him and compelled him, in June, to sign the Magna Charta. This contained no new principles, but was a written acknowledgment of the rights of the vassals. From it were gradually deduced two great English principles—that no one should suffer arbitrary imprisonment, and that no tax should be imposed without the consent of the council of the nation. The charter was frequently confirmed and its terms took on a broader meaning until it became the "palladium of English liberties." Twenty-five barons were constituted a committee to see that the provisions of the charter were observed. John, however, had no intention of keeping his agreement, and the Pope annulled the charter and excommunicated the leaders in the revolt. The barons then offered the crown

to Louis, son of Philip Augustus, who landed in England. Before a decisive combat took place John died, Oct. 19, 1216. See MAGNA CHARTA.

His son, Henry III (1216-72), who was a mere boy, was crowned, and the English barons rallied to his support. Louis was driven from the kingdom, through the efforts of the Justiciar Hubert de Burgh (q.v.), and England was saved for the English. For 11 years the country was well governed by William Marshall and Hubert de Burgh. Then ensued a period of misgovernment under Henry's personal rule. He confirmed the charter repeatedly, but never kept his promises. He favored foreign nobles, allowed English livings to be given to Italians, and was wholly subservient to the Pope. In 1258 the barons, exasperated by his conduct, met in the so-called "Mad Parliament." They were led by Simon de Montfort, the King's brother-in-law. They demanded a better government and the observance of the charter. By the Provisions of Oxford (q.v.), which they enacted, the government was transferred from the King to a council of barons. Their rule was not successful, however, and in 1264 Louis IX of France, who had been asked to be the arbitrator between the King and the barons, gave his opinion in the so-called *Mise of Amiens* that the provisions were illegal. Civil war ensued. Henry was defeated at Lewes (1264), and by the *Mise of Lewes* the King was compelled to agree to the demands of the barons. The following year Simon de Montfort, who was the real ruler, called a Parliament, to which burghers were summoned, as well as the barons, clergy, and knights of the shire. This precedent was followed later by Edward I. In the same year Simon was killed in the battle of Evesham, in which the baronial forces were overthrown by the King's troops, under the command of Prince Edward. Simon's son and some of the barons continued the struggle for about a year longer, but all parties were weary of the strife and longed for peace. Under the "Ban of Kenilworth" they all surrendered, and in 1267 Henry, by the "Statutes of Marlborough," granted almost all their demands. Peace followed, and Edward I (1272-1307) inherited a united kingdom. He ruled justly, in accordance with the charter and with the aid of Parliament. In 1298, by the *Confirmatio Cartarum*, he agreed that no tax should ever be levied except by common consent. From this time the government was to be managed conjointly by the sovereign and Parliament. The latter Edward had strengthened by summoning, in 1295, the "Model Parliament," which was composed of the tenants in chief, representatives of all classes of the clergy, knights of the shires, and two citizens from each city or borough. By his other laws Edward attempted to restrict the power of the clergy and of the barons. The most noted were the "Statute of Winchester" (1285), which renewed the "Assize of Arms"; the *Quia Emptores* (1290), which restricted subinfeudation; and the "Statute of Mortmain" (1279), which forbade the acquisition of land in "mortmain" by the church. Edward is frequently called "the English Justinian." He subdued Wales between 1277 and 1283, and Edward II, born in Carnarvon Castle (1284), received the title of Prince of Wales, which has been borne by the heir apparent ever since. In 1290 the Jews were expelled from England. Edward claimed the overlordship of Scotland as a preliminary to his acting as arbitrator between the various

claimants to the throne, and received the homage of Baliol, to whom the crown was awarded, in 1292. The Scotch, however, rose in resistance under great leaders like Wallace and Bruce, and Edward's incompetent son and successor, Edward II (1307-27), proved unequal to the task of retaining his father's conquests. After various wars (see SCOTLAND), the principal event of which was the battle of Bannockburn (1314), by the Treaty of Northampton, in 1328, the independence of Scotland was acknowledged. Edward II was a weak ruler, who spent his reign in a continuous struggle with the barons. The general result was a weakening of the royal authority. His wife, Isabella, and her lover, Mortimer, headed a rebellion against him, and were joined by Prince Edward. The unfortunate King was deposed by Parliament in 1327, and was soon afterward murdered. Edward III (1327-77) attempted unsuccessfully to regain authority over Scotland, which was aided in the contest by France. The attitude of France was one of the causes which led to the Hundred Years' War (q.v.). In addition, Edward feared that he might lose Gascony, the most important French possession which England had, and that Flanders, the great wool market for England, might be seized by the French King. He therefore laid claim to the French crown, as the grandson of Philip IV. As his descent was through the female line (see SALIC LAW), his claim was not held by the French to be legally good; but it was sufficient as a cause for war. The first period of the war was distinguished by the great English victories of Crécy (1346) and Poitiers (1356), and ended with the Peace of Bretigny (1360). By this treaty Aquitaine was ceded to England, and Edward abandoned his claim to the French crown. His wars compelled him to seek aid constantly from Parliament, and to grant to it more extensive powers. In the midst of the war England was visited, in 1348 and 1349, by the terrible scourge of the Black Death, which is said to have destroyed more than one-third of the population. Labor became scarce, and the "Statute of Labourers" was enacted, for the benefit of the landlords, in 1349, to prevent the peasants from demanding higher wages and to compel them to perform their services as villeins. This caused great discontent, which was fomented by the preaching of the Lollards (q.v.), the followers of John Wiclif. Edward III was succeeded in 1377 by Richard II. The collection of a poll tax in 1381 led to the Peasants' Revolt, in which Wat Tyler was one of the leaders. The revolt was suppressed with great cruelty by the nobles. Richard II was under the control of the great barons, except for brief periods of personal rule through favorites, until 1389. The barons were determined to wrest all authority from the King, and in the "Wonderful" or "Merciless Parliament" (1388) impeached the King's advisers. But the following year Richard secured full authority, and ruled in accordance with the Constitution until 1397. In the meantime the Hundred Years' War had been dragging on, having been renewed in 1369, and the French had reconquered Aquitaine. Richard was bent upon a French alliance, not a war, and in 1396 married Isabella, the eight-year-old daughter of King Charles VI of France. This marriage, and his surrender of Brest and Cherbourg to the French, incensed his subjects. The surrender was just, as these cities had been pledged

to him as security for a debt, and the debt had been paid; but his subjects did not understand this, and thought that he was sacrificing English interests. Moreover, his revenge, in 1397, on the leading members of the baronial party, for which he had been biding his time, raised up many enemies. While Richard was absent in Ireland, in 1399, Henry Bolingbroke, Earl of Hereford, the son of John of Gaunt (Duke of Lancaster, fourth son of Edward III), landed in England and was joined by many of the leading nobles. Richard was compelled to abdicate in 1399, and Hereford was chosen King by the Parliament as Henry IV. Thus Parliament asserted the right to regulate the succession, and the house of Lancaster obtained the crown. Before leaving the reigns of Edward III and Richard II, it is necessary to notice their long series of laws directed against the pretensions of the papal curia. By the "Statutes of Provisors" (1351 and 1390), the Pope was prevented from disposing of English livings. By the "Statutes of Præmunire" (1353 and 1393), the powers of the curia were greatly restricted, and Englishmen were subjected to severe penalties if they appealed to the curia or obtained bulls from Rome. The "Statute of Mortmain" was also reënacted, in substance, in 1392.

The reign of Henry IV (1399-1413) was marked by a strict adherence to constitutional forms, by frequent rebellions, and by the persecution of the Lollards. As he owed his title wholly to Parliament, Henry felt obliged to pay to it due deference; and, as he had received aid as a champion of the church, he thought it necessary to persecute heresy. The statute *De Heretico Comburendo* was passed against the Lollards in 1401, and in the ensuing years some were burned. The rebellions were caused by the adherents of Richard. The most noted was the conspiracy of the Earl of Northumberland, his son, Harry Percy, surnamed "Hotspur," and Owen Glendower. This was crushed in the great battle of Shrewsbury (1403). The reigns of Henry V (1413-22) and Henry VI (1422-61) were notable mainly for the continuation of the Hundred Years' War. Henry V had renewed the claim to the French crown. The claim was popular in England, as the war was looked upon as a national one. The brilliant victory of Agincourt (1415) flattered the national pride. In 1420, by the Treaty of Troyes, Henry was declared heir to the French throne. His early death, leaving only an infant son, Henry VI, frustrated all the hopes of the English, although the royal infant was crowned King of France, and the English held most of the French kingdom. The marvelous career of Joan of Arc (q.v.) and a general national rising in France caused the loss of all the French possessions except Calais in 1453. The mental incapacity of Henry VI and the ill success of the French war caused the house of York to put forward a claim to the throne, which resulted in the Wars of the Roses. (See ROSES, WARS OF THE.) It is impossible to enter into the details of these wars, in which there were frequently apparent reconciliations and alternate victories. Edward, Duke of York, was proclaimed King, as Edward IV, in 1461, and reigned until 1483, although Henry VI was restored for a time in 1470-71, through the efforts of the Earl of Warwick, the great kingmaker. Edward V, son of Edward IV, became King on the death of his father, but the throne was almost immediately usurped by

Richard III, brother of Edward IV. In 1485 Richard met his death on Bosworth Field, when Henry Tudor, Earl of Richmond, invaded England. The long war had thus caused two changes of dynasty—from Lancaster to York, and then again to Lancaster or Tudor. Almost all of the old nobility were destroyed while fighting on one side or the other. The crown obtained great wealth through confiscation of the property of its opponents, and was thus rendered independent of parliamentary grants. Consequently, Parliaments were seldom summoned. There was much illegal taxation, in the form of enforced "benevolences," or gifts from the subjects. This period paved the way for the despotism of the Tudors.

With the union of the houses of Lancaster and York by marriage under Henry VII (1485-1509), the modern period for England begins to dawn. The great nobles having exterminated themselves in the Wars of the Roses, during which wars the House of Commons had become the mere tool of opposing factions, there was room for that increased strength of royal power which marks the beginning of the modern epoch. By enforcing the law of livery and maintenance, Henry VII kept the nobles, while his court of Star Chamber gave justice to the weak against the strong, in cases which the ordinary courts could not reach. He levied illegal taxes, called "benevolences," from the richer classes without consent of Parliament. Henry's hold on the throne was for twelve years. Frequent and serious disturbances by Yorkist pretenders marred a reign generally characterized by peace and economy and marked the beginning of an extensive commercial development. In 1497 John Cabot sailed from Bristol and secured for England the credit of the discovery (or rediscovery) of the mainland of North America. It was during Henry VII's reign that the Renaissance began to prevail in England, which had not developed there as early as on the Continent, owing to the unsettled conditions resulting from the constant civic strife of the previous reigns. Henry VIII's reign ushered in the Reformation.

The origin of the Reformation in England was the divorce which Henry VIII (1509-47) desired to have from his wife, Catharine of Aragon. Failing to secure this from Pope Clement VII, he had the English clergy and some of the European universities declare the marriage void, and married Anne Boleyn. He found in his able minister, Thomas Cromwell, in Thomas Cranmer, Archbishop of Canterbury, and in a subservient Parliament, which sat from 1529 to 1536, the willing agents of his schemes. Parliament passed a series of acts completely separating the Church of England from Rome, rendering the inferior clergy amenable to the civil courts, and placing the laws, as well as the actions, of the clerical convocation under the King's control. Chief of these acts was the Act of Supremacy, in 1535, appointing the King "Protector and only Supreme Head" of the Church of England. In 1536, the smaller monasteries were suppressed and a translation of the Bible was authorized; in 1538 relics and images were destroyed and in 1538-40 the greater monasteries were suppressed. Nevertheless the Six Articles of 1539 enforced conformity with the chief doctrines of the Catholic church. Henry VIII's ecclesiastical policy was intimately connected with his numerous marriages, and resulted in changes far beyond what he or his advisers contemplated. His own

motives were mainly selfish and sensual. He squandered his father's enormous hoard, plundered the church, debased coinage, and left the kingdom poor. The confiscated church property he bestowed on favorites, founding a new aristocracy and gentry, who were later the mainstay of the Tudor dynasty. But these were harder masters than the conservative monasteries, and inclosed the common pasture and arable lands into sheepwalks, turning out the peasantry, and otherwise disregarding their time-honored customs. This made the Reformation unpopular with the masses.

Under Henry's successor, Edward VI (1547-53), a minor, the reformation of doctrine followed. The First Book of Common Prayer (1549) established a uniform service in the English language. The Second Book of Common Prayer (1552) was a more marked advance towards Protestantism, and the Forty-two Articles (1553) were even Calvinistic in tone. But these were without consulting the people, and ministers and courtiers using the Reformation only for private gains, and made it still more unpopular. Two rebellions occurred—Jack Kett's rebellion against the inclosure of the common lands in Norfolk, and another in Cornwall and Devon against the Reformation itself. Under Mary (1553-58), a devout Catholic, the reaction came. The Parliament of 1553 restored Catholic worship, but was unwilling to return confiscated church property and to tolerate the subordination of England to Spain by Mary's proposed marriage to Philip. An attempted rebellion under Sir Thomas Wyatt and the Duke of Suffolk was suppressed, and the Queen married Philip of Spain. In 1555 Parliament repealed the laws of Henry VIII, thus reuniting the Church of England with Rome. In the persecution of the Protestants that followed, nearly 300 victims are said to have been burned, Bishops Ridley and Latimer and Archbishop Cranmer among them.

The policy of Elizabeth (1558-1603) was a compromise between the radical and reactionary tendencies of her predecessors. By the Act of Uniformity (1559) the use of a new prayer book, based on that of Edward VI, was established, and the Act of Supremacy (1559) made her the "supreme governor of the Church." The Thirty-nine Articles (1563), a revision of the Forty-two Articles, fixed the final constitution of the Anglican Church, with Protestant dogmas, but with a retention of the hierarchy, and in part of the cult, of the Catholics. But above all else the church was national. Archbishop Parker was the chief instrument in bringing about this desired result. The advice of her able minister, William Cecil, enabled Elizabeth to handle political questions with equal success. On the Continent she aided the Protestants in their struggles against the overwhelming power of Spain, especially in the Netherlands. The Invincible Armada, sent in 1588 to subdue England, was defeated by Howard and Drake, and Elizabeth became the acknowledged head of the Protestants of Europe. At home she was equally successful, ruling in harmony with her people, though not always agreeing with Parliament. The economic legislation of her reign was so well founded that it lasted nearly two centuries. Navigation laws built up a marine, corn laws aided agriculture, and the great trading companies, like the Muscovy, Eastland, Levant, and East India companies, exported English productions and brought

wealth to England. The Renaissance bore fruit in the most brilliant of English literary epochs. See ENGLISH LITERATURE.

On the death of Elizabeth the house of Tudor was succeeded by that of Stuart, the crowns of England and Scotland being united under James, the son of Mary, Queen of Scots. In striking contrast with the preceding reign, that of James I (1603-25) presents constant quarrels with the people at home and incapacity abroad. James believed in the "divine right" of kings, but not in absolute monarchy. A majority in Parliament sought not parliamentary supremacy but some division of power between King and Parliament. The King was conceited and lacking in tact and judgment; the Puritans in Parliament had advanced views regarding popular government. In the first dispute (1604) James declared that there were no privileges which Parliament could enjoy except by the favor of the King; while the House of Commons held that "They did not ask for anything that was not in accordance with justice, and they did not demand a single privilege that was not necessary for the good of the nation as well as for their own dignity." In the Great Protestation of 1621 Parliament asserted its right to debate on state affairs and advise the King concerning them. Although the authorized translation of the Bible was made in his reign (1604-11), he thwarted the general desire for greater liberty of Protestant practice in the church and favored the hierarchy. "No bishop, no king," was his motto. He forced an unpopular episcopacy on Scotland. His unwise attempt to obtain a Spanish marriage for his son brought on a useless and expensive war. The inglorious conduct of this war, and of another against France, waged by his favorite Buckingham, by draining the royal coffers, helped to bring on the Puritan revolution.

Unable to obtain supplies without redressing the grievances of Parliament, James's son, Charles I (1625-49), raised forced loans, imprisoning those who refused. In May, 1628, Parliament passed the Petition of Right, in which all forms of taxation without consent of Parliament were prohibited; there should be no martial law in time of peace, and no one should be imprisoned except on specific charges. Charles was obliged to assent, but on the remonstrance against his levying tunnage and poundage, prorogued Parliament. After the stormy session of the following year, he ruled for eleven years without Parliament, raising money by illegal and questionable methods. His chief ministers were Thomas Wentworth, an able but intolerant and uncompromising man, who reduced Ireland to order and obedience, and Archbishop Laud, who attempted to enforce church uniformity by the observance of a high ritual distasteful to the people. The King's instrument of judicial oppression was the Star Chamber (q.v.), composed of the Privy Council and two justices, while the ecclesiastical commission attended to the Puritans. An attempt to force a new ritualistic prayer book on Scotland caused the abolition of the episcopacy, liturgy, and canons there, and an armed invasion with which Charles was unable to cope. He was forced to call a Parliament and ask for supplies. When that body insisted first upon a redress of grievances he dissolved it after a session of only three weeks. But the Long Parliament was convened the same year (1640). Led by Pym and Hampden, it passed an act of attainder

against Wentworth, now Earl of Strafford, who was executed, and abolished both Star Chamber and ecclesiastical commission. Another act forbade the King to dissolve the existing Parliament without its own consent. In 1641 came the Grand Remonstrance (q.v.) and the impeachment of the bishops; and Charles's ill-advised attempt to seize the five leaders of the opposition and the struggle between King and Parliament to control the militia hastened the now inevitable war, which opened with the indecisive battle of Edgehill in 1642. The Scotch were drawn into the struggle, Parliament adopting their Solemn League and Covenant. Reorganized on the New Model (q.v.) by Cromwell, the Parliamentary army bore down all before it. At Marston Moor and Naseby the King was hopelessly beaten. In 1646 Charles became a prisoner of the Scotch, by whom he was handed over to Parliament; his execution took place on Jan. 30, 1649. But the army, which was independent in religion and desired toleration of the sects, came into conflict with the intolerant Parliament, which was Presbyterian. "Pride's Purge," Dec. 6, 1648, turned out 143 Presbyterian members. England was declared a commonwealth in 1649. The army under the lead of Cromwell crushed the rebellion in Ireland with great bloodshed, and beat the Scotch, who had risen for Charles II. The inevitable result was that the army ruled supreme. Oliver Cromwell, its general, was declared Lord Protector in 1653, and ruled with subservient parliaments till his death (1658). His policy was the French alliance against Spain, a war for commercial supremacy with the Dutch, and toleration for all except Catholics at home. Repeated rebellion, however, forced him to withdraw toleration from Episcopalians. On the death of Cromwell, in 1658, his son Richard was named Protector. He abdicated in the following year. In 1660 General Monk marched upon London and put an end to the Puritan régime.

With the Restoration came reaction against the austere morality of Puritan times. Charles II (1660-85) lived chiefly for pleasure. His advisers were in the main men of much the same type, most of them, like him, being in pay of Louis XIV of France. Two ruinous wars with Holland were waged in the interests of that power. Internal legislation was reactionary. Acts were passed compelling magistrates and municipal officers, clergymen, fellows of the universities, and schoolmasters to conform with the Established church, and ministers who refused were forbidden to come within five miles of an incorporated town or their former parishes. In 1673 the Test Act was passed, excluding Catholics and Nonconformists from public offices. A fictitious popish plot resulted in disgraceful persecutions of the Catholics on the testimony of Titus Oates (q.v.), a perjurer. Attempts to exclude from the throne the Duke of York, who had embraced Catholicism, failed through the King's opposition. By unscrupulous use of the courts, the charters of all boroughs were confiscated and remodeled in the King's interest. The Habeas Corpus Act, however, insuring a fair trial to every prisoner, was passed in 1679. The three years of James II's reign (1685-88) were taken up with an attempt to restore the Roman Catholic religion chiefly by illegal means. By his power of dispensing with the law, he set at naught the Test Act, and forced Catholics into

the universities, the army, and even into the royal council. He also gathered a standing army to further his designs. Failing to secure toleration for Catholics from the Established church, he tried to form an alliance with the Dissenters, but only with partial success. His illegal proclamation of indulgence was resisted by the bishops, whom he tried in vain to convict of libel. The birth of a male heir, with the prospect of a perpetuation of his tyranny, wore out the public patience. Seven of the most influential men of England invited William of Orange to invade the country. His mere appearance was enough to overthrow the government, and James fled to France.

The Development of Cabinet Government. William III was the husband of Mary, the eldest daughter of James II. The Convention Parliament of 1689, which was assembled to determine the succession, offered the crown to William and Mary conjointly, accompanying the offer with the Declaration of Right. This document, embodied in the famous Bill of Rights, put an end to the dispensing power as used by James, enacted that no Roman Catholic could wear the crown, and established the supremacy of statute law over the King's proclamations. The theory of the Restoration had been that the King and Parliament were coördinate in power and should act in harmony with each other; but this had been demonstrated to be impossible by the reign of James II. Henceforth the King's ministers were answerable to the House of Parliament, and cabinet government began. The ministers were now changed in accordance with the political complexion of the House of Commons. Although William III had frequent cause for provocation from the corrupt politicians of his day, he maintained a wise and moderate domestic policy. The Toleration Act gave Dissenters freedom of public worship. In 1694 triennial Parliaments were provided for, and the Bank of England was founded. William's foreign policy involved England in two long wars against France under Louis XIV, for the second of which he had just prepared when an accident terminated his life (1702). His successor, Queen Anne (1702-14), was a good-hearted woman, of no ability. During the first part of her reign she was under the influence of the Duke of Marlborough. On the Continent he continued William's policy, leading the allied English, Dutch, and German forces to brilliant victories over the generals of Louis XIV, especially at Blenheim and at Malplaquet, which forced Louis to sue for peace. In 1707, before the end of this war, the legislative union with Scotland was accomplished. Forty-five Scottish members were added to the Commons and sixteen to the Lords, but Scotland retained her own law, church, and fortresses. For the history of the United Kingdom, see GREAT BRITAIN and the authorities there referred to.

ENGLAND, BANK OF. See BANK, BANKING.

ENGLAND, CHURCH OF. The dominant religious body in England, for the greater part of her history the established church of the country. It is necessary to bear in mind the prior existence of a *British* church which, like the British nation, was subsequently either uprooted, subdued, or assimilated in part—a fact which has an important bearing upon the claims which are made as to its antiquity and continuity. The exact date of the introduction of Christianity into Britain is not known. Gildas, a British author of the sixth century, believes that it was as early as the year 37. There is no sound historical ground for asserting that the island was ever visited by an apostle. There is some ground for believing that the new religion was found there about 170, having come either from Rome.

When we reach the fourth century, we are treading on firmer ground. The records of the Council of Arles (314) actually give us the names of three bishops as present from Britain: Eborius of York, Restitutus of London, and Adelpheus or Adelfius, either of Caerleon in Wales or of Lincoln. If the Caerleon theory be accepted, these sees would correspond with the Roman provinces into which the country was divided.

In the early days of eager controversy it is evident that the British church adhered in doctrine and discipline to the orthodox side, although, of course, there were some who were tainted with heresy. Indeed, there seems to be no doubt that Pelagius was a native of Britain. It is difficult to determine whether the Britons appealed to Rome or to the bishops of Gaul for assurance as to the true doctrine. To whichever the appeal was made, a matter not within the scope of this article to determine, the fact makes evident the anxiety of the British Christians to guard their orthodoxy.

After the overthrow of Pelagianism a more dreadful foe was encountered in the persons of the Saxons and Angles, whose successful invasion drove the Britons to the western part of the island, leaving the eastern part heathen.

The outlook for the church at the end of the sixth century was gloomy enough. Then it was that Gregory the Great, moved by the sight of the English lads in the slave market at Rome, undertook the conversion of the island and sent thither, in 597, Augustine and his fellow missionaries. Upon their arrival they found several bishops, whom they endeavored, but in vain, to bring into union with the church on the Continent. Much is due to them, for doubtless their mission wrought great changes in behalf of Christianity. By the death of the Christian King, Ethelbert of Kent (baptized by Augustine,

possibly through the influence of his Christian Queen, Bertha), and the succession to the throne of his irreligious son, Eadbald, the church received a severe blow, from which his conversion enabled it to rally. For many years her history was one of varied successes and failures. Largely by means of Irish and Scottish missionaries (among whom were Colomba, Aidan, and Finan) and of Mercians and Saxons, commissioned by Irish-born enthusiasts, the church had been planted more or less firmly in all the English kingdoms. At this time there was no national unity—no one Kingdom of England. Likewise there had not been as yet in the church any fusion of the British and Roman parties, each of them maintaining with great tenacity its own ecclesiastical uses. One of the chief points of dispute was the proper date for Easter (q.v.). At length, in the conference at Whitby (664), the Roman party gained the ascendancy. Thus it was made more easy for Theodore (who in 668 succeeded to the primacy and was one of the great men of his day) to unite the churches of the several kingdoms into what may properly enough be called the national Church of England. It follows, therefore, that the church is in no way indebted to the state for its original establishment and independence—being really the older institution of the two, by three centuries. Instead of the state establishing the church, it may more fairly be said that through its unification the church established the state. The Council of Hertford in 673 was not only the first ecclesiastical gathering, but the first assembly of any kind for the whole of England.

Theodore had not long succeeded in effecting this confederation before he began to act almost as though supreme over the other English bishops. In Wilfrid, Bishop of York, he met a prelate of consummate talents and determination, who would not allow the claims of any one to supremacy over him. When Theodore undertook, without his consent, although supported by King Egfrid, to carve new dioceses out of Wilfrid's jurisdiction, he at once appealed to the Bishop of Rome. This is the first of such appeals from England of which we have any record. He obtained from Agatho, the Roman Bishop, an order to Theodore for the rectification of these diocesan lines, with the threat of deprivation or excommunication for any clergyman or layman who might disobey the mandate. The King, however, imprisoned Wilfrid and allowed Theodore to go unchecked in his schemes of organization, for which he seems to have had uncommon genius. To him is attributed the origin of the parochial, or perhaps, rather, of the diocesan, system, as well as the first regular provision for the payment of tithes and offerings, not to the bishop, but to churches which the laity had built; and, further, of giving to such laymen the right of patronage, or of presenting clergymen to certain cures. After his death, the relations between the church and the state grew more distinct and defined, the latter agreeing to protect the former in its temporalities and supremacy. The church became more and more the religious function of the state and furnished the most efficient means for welding the different kingdoms into one.

But before this, as has already been shown, it had become the church of the nation, not by any act of the yet unformed nation, but by the manifold action of various individuals who had converted their several properties, however they lay, into parishes and had themselves provided

for the support therefrom of the required number of clergy. By universal custom, therefore,—not at first by law—this voluntary support was afforded; sometimes by payment in kind, sometimes in land, sometimes in tithes, and afterward by endowments and entailed tithes and testamentary donations. These benefactions have in many instances been preserved and continued through successive generations, and many similar ones have been added from time to time. It follows, therefore, that the church is no more indebted to the state for its endowment than for its establishment.

The period of the Danish inroads and conquests, which began about the close of the eighth century, was one of sore calamities to the church. These were somewhat mitigated by Alfred, who promulgated ecclesiastical laws, established schools, and provided books, some of them translations of his own. During the reign of Edgar (958-975) began the fierce and long-continued struggle between the monks and the parish clergy—the regulars and the seculars—in which Dunstan was so conspicuous. The influence of the secular clergy began, after his death, to overshadow that of the monks, who had at first been in the majority. Canute did something to restore the integrity and prosperity of the church, which had been seriously impaired by the scandalous conduct of bishops and others. With the accession of Edward the Confessor (1042), who had spent most of his life in Normandy, came a great influx of foreign prelates, with the habits peculiar to their own countries. This gave rise to much friction in ecclesiastical affairs, and disputes arose between the native and foreign clergy, in which Stigand, Archbishop of Canterbury (c.1052-70), took a prominent part. Edward's policy was carried out still more widely by William the Conqueror, who allowed the papal legates to depose Stigand and summoned Lanfranc, one of the most distinguished theologians of his day, to the vacant see. He and Ealdred, Archbishop of York, had a long and earnest dispute as to the primacy of Canterbury, which historically there was no room for York to dispute, and which was finally allowed at a council held at Windsor, in 1072, when the precedence of other sees was settled.

It was during the reign of the Conqueror that the civil and ecclesiastical courts were held separately—a change that tended to the benefit of both church and state. The same monarch caused the compilation of the Domesday Book, which showed that about half of all the lands of the kingdom were at the time in the hands of spiritual persons. In many cases the same possessions have been the property of the church for nearly 1000 years. It is also true that nearly all its present property was acquired either before the Norman Conquest or since the Reformation. The eleventh century was a period of great activity in building cathedrals and other churches, among which were those of Canterbury, York, Lincoln, and St. Paul's. Westminster Abbey was consecrated a few days before the death of Edward the Confessor, in 1065.

William Rufus openly encouraged simony, which the Conqueror had abhorred, and thus the church became greatly demoralized. Anselm appeared in due season to arrest its downward course and by his courageous and notable contests did much to prevent the King from

usurping its spiritual rights and privileges. To him is due also the credit of an earnest attempt to deal with scandals within the church. Anselm's defense of the church against William Rufus was but a prelude to the greater contest in Henry II's reign.

In the twelfth century the church began, in imitation of the Code of Justinian, to compile a code for itself. In the middle of the same century the great conflict was fought out between the church and the state as to the authority of the latter to deal with clergymen guilty of serious offenses. In this bitter contest Thomas à Becket played a very prominent part. He had been the confidential secretary of the Primate for some time and was Archdeacon of Canterbury at the time of the accession in 1154 of Henry II—"half monk, half soldier," as he was called. After serving for a while as chancellor, Becket succeeded Theobald as Archbishop of Canterbury in 1162, and it was not long before the controversy between the King and himself began which was only terminated by his cruel murder in his own cathedral in 1170. Partly because of the general horror following this crime and of the King's own remorse, and partly because of the elevation by the multitude of the Archbishop into the number of saints, the influence of the Constitutions of Clarendon (1164), which Becket refused to sign as restraining the authority of the church, in making the clergy amenable to the civil courts, was greatly impaired. Subsequently the King surrendered everything in this direction for which he had been contending, and it seemed that strife between the ecclesiastical and civil powers, after so portentous a conflict, was ended.

During this century and the following one the Crusades, which had first been preached in the days of Anselm, attracted many recruits from England, and the monastic spirit was evidenced in the establishment of military religious orders. The Knights Templar and the Knights of St. John were the only ones that obtained any foothold in England. The Crusades led oftentimes to the sale of lands to the monasteries that their owners might obtain the means for their expeditions, and not a few churches were built and restored in fulfillment of their pious vows.

After the martyrdom of Becket there was a long vacancy in the primacy, caused largely by the claim of Odo, the prior of Christ Church, Canterbury, that the election should be left to the monks. The power of the Roman Bishop had meanwhile been growing, partly from the desire of the kings to strengthen their disputed claims to the throne by obtaining the powerful influence of the Pope, as also from a desire to have him side with them against the recalcitrant bishops and other clergy. During the reign of King John the contest between the church and the throne broke out anew over the appointment of Stephen Langton to the see of Canterbury. John obstinately refused to acquiesce in the Pope's decision favoring Langton's election to the see, and deputed the papal envoys sent to adjust the difference between pontiff and sovereign. The Pope in consequence laid an interdict upon the whole kingdom, which lasted more than six years, and John only yielded under threat of deposition.

Stephen Langton, Archbishop of Canterbury (died 1228), stood with the barons against both monarch and pontiff in the demand for Magna

Charta. For the Magna Charta, extorted from King John, England is more indebted to the church than to any other agency. Indeed, it is doubtful whether without its aid any such guaranty of liberties would then have been obtained. Translated into English, its first clause runs: "The Church of England shall be free, and hold its right entire, and its liberties inviolate."

During the reigns of the thirteenth century there was much controversy over, and protest against, the frequent levies of tallage, an ecclesiastical tax for the support of the papal see. The popes resorted to this tax at large to replenish their exhausted coffers. So frequent were these calls that the English clergy found them very burdensome and protested vigorously, but to very little effect. Numerous protests also arose in England over the papal nominations of foreigners to English benefices, which had resulted in many abuses.

The clergy, as a rule, were treated harshly by Edward I, whose pecuniary exactions from them led to continued irritation. Under Edward II the limits between the ecclesiastical and civil jurisdictions were defined by the statute called *Articuli Cleri*. By the statute of *Præmunire*, passed in the reign of Edward III (in 1351), the nationality of the Church of England was for the first time recognized and guaranteed by civil law. To this period belong Wiclif and the Lollards, whose influence upon the Reformation is well known.

Throughout the fourteenth century the popes continued to assert their authority in various ways, but the great schism of the West, which divided Christendom over the claims of rival popes, greatly weakened the prestige and authority of the Roman pontiffs in England as well as elsewhere in Europe. In England the duration of the schism had allowed the statutes of *præmunire* to be executed with but little opposition. The ecclesiastical confusions resulting from this schism contributed much to prepare the way for the religious changes of the sixteenth century. In treating of that period technically styled the Reformation (q.v.) one must not confine the review to the reign of Henry VIII. The movement extended also over the three subsequent reigns of Edward VI, Mary, and Elizabeth. That some kind of reformation was greatly needed, in the interests of both church and state, was generally admitted. There was, however, much difference of opinion as to how it could best be accomplished. Where so many were interested in the work, and with such a variety of motives, it is not surprising that the results should have had about them a mixture of good and bad. Among the chief points to which the reformers took exception were the papal supremacy, enforced clerical celibacy, worship of images, invocation of saints, indulgences, compulsory auricular confession, and transubstantiation. When Henry VIII became wearied of the delay on the part of the Pope (Clement VII) in granting him a divorce from Catharine of Aragon, his brother's widow, he appealed to Cranmer, the newly appointed Archbishop of Canterbury, who, acting under the Statute for the Restraint of Appeals passed by Parliament in 1533, in concurrence with many divines and casuists and several European universities, declared the marriage null and void (1533). His opinion was also approved by the English Convocation. Henry then married Anne Boleyn, and pres-

ently the Pope pronounced his first marriage lawful and excommunicated him for adultery. The King now turned a deaf ear to Rome's anathema, and Parliament proceeded, under royal command, to enact laws formally renouncing the papal supremacy. Convocation (which then met simultaneously with the Parliament, that ecclesiastical laws might receive the joint sanction of the two bodies) concurred in this action. An appeal was made from the Pope to a general council, and in its course the assertion was made that "the Bishop of Rome hath not any more authority conferred upon him by God in Holy Scripture, in the realm of England, than any other foreign bishop." Doubtless, some of the clergy were moved to this action not so much by their real sentiments as by dread of death if they demurred. Under the auspices of Cranmer, and with the King's approval, an English version of the Bible was published.

The monarch's worse side was shown in his dissolution of the monasteries and the squandering upon himself, the nobles, and the gentry of the larger part of the wealth which thus fell under his control. Hence, under bereavement of so many sources of charity, came those formidable risings of the people which more than once threatened the royal armies with defeat. Indeed, the Reformation was hindered more by the selfishness and treachery of its pretended friends than by the opposition of its enemies.

The reign of the youthful and pious Edward VI (1547-53) was long enough to allow a vast amount of sacrilegious plunder. The first book of *Homilies* was set forth in 1547, and the next year an *Order for the Communion* in English. This was followed by the first English Liturgy, which was used for the first time on Whit-Sunday, 1549. The second book of Edward was issued in 1552, but never received due authorization. In the same year the Forty-two Articles of Religion were set forth, but they were not sanctioned by Convocation until 1563, when they were reduced, with some modifications, to 39. Parliament revoked the Six Articles of Henry, authorizing clerical marriage, enjoining communion in both kinds, prohibiting solitary masses, and abolishing divers usages and ceremonies which were then believed to foster superstition and idolatry. The death of Edward, in 1553, put both the Reformation and the reformers to a severe test. Under Mary the Pope was once more acknowledged, and the peculiar doctrines of Rome were reinstated, though Mary retained the title "Supreme Head." Cranmer, Latimer, Ridley, and many others sealed their convictions with their blood. Upon Elizabeth's accession (1558) this work of reconstruction was continued under more favorable circumstances. The new Queen and her Parliament showed clearly enough their determination not to push ecclesiastical changes to the lengths some of the reformers demanded. She had no sympathy with the eccentric course of the foreign reformations. Under their influence some of the English reformers began to look upon what had already been completed as but partial, and introductory to other changes thought by them to be equally essential. From this source arose the prolific evils belonging to that Puritanism which wrought as great damage as the Erastianism with which much of the previous work had been accompanied. Elizabeth

herself had little religious sentiment, and questions of state determined her policy to abet and foster the Reformation movement. But she had no liking for the Puritanical spirit, which boded a curtailment of the prerogatives of the throne and an assertion of rights which might trench upon the privileges of Tudor absolutism. While seeking to hold Puritanism in check, nevertheless, her ministers understood its value to the Queen and judiciously maintained a balance between the retroactive and extreme reforming parties. There was still considerable religious controversy, in which "the judicious Hooker" took a prominent part. Archbishop Parker—a thoroughly loyal prelate, a scholarly man, and an efficient organizer—belongs to this same period. The almost unanimous conformity—less than 200 clergymen quitted their benefices at Elizabeth's accession—was, no doubt, due in part to the severe penal laws which the Queen enforced. There was no visible nor formal schism until the Pope, finding Elizabeth deaf to his appeals and determined in her refusal to acknowledge his supremacy, formally excommunicated her and absolved her subjects from allegiance to her. Thus encouraged, the papal adherents began to separate themselves into a distinct community in the year 1570. They had, however, for nearly a century no bishops of their own, except for six years, when a titular bishop, sent from Rome, resided in England.

The Puritans, failing to bring the church to their way of thinking, cut themselves off from her communion and set up communities of their own. Having, notwithstanding Archbishop Whitgift's earnest struggle against them, secured a majority in both Houses of Parliament, they passed an ordinance to establish a Presbyterian form of government. The Prayer Book and episcopacy were practically abolished for a season, despite the brave and determined protests and opposition of nonconforming churchmen. Convocation in 1563 settled and subscribed the Confession of Doctrine which has ever since remained an authoritative apologetic document of the English church. It also set forth, with synodical authority, a second Book of Homilies.

James I did not prove very serviceable to the Puritans, although he was not always reliable in his support of the church. He restored the episcopate to his native Scotland and ordered a revision of the English version of the Holy Scriptures. The reign of Charles I and Archbishop Laud—for the King and prelate may rightly enough be joined together, such was their agreement generally in character and policy—was a period of great unrest to the church. Their devotion to her interests and their sacrifices in her behalf cannot well be doubted or belittled, however much it is to be regretted that the one was lacking in firmness and the other in conciliatoriness. Their unselfishness and moral courage joined them together again in an honorable martyrdom.

The period of the Commonwealth may well be described as one of religious anarchy; and yet with such men as Cromwell in power it may be that this very lawlessness was more to the advantage of the church than any system which they could have put into operation. Of the varied mischief and cruelty to the church perpetrated during this period, there was ample evidence everywhere; and the senseless and pro-

fane damage done by or under Cromwell's order is still visible in cathedrals and churches throughout the kingdom.

On the restoration of Charles II (1660) the persecutions and other outward disasters to the church came substantially to an end; and she began once more to go on with her work quietly and prosperously. No period, perhaps, furnished a richer company of learned and godly divines, among whom may be mentioned Sanderson, Jeremy Taylor, Barrow, Pearson, and Bull, who were worthy successors of Jewel, Hooker, Andrewes, and Hammond.

The peace of the church was again disturbed by the efforts of James II to reestablish the papal supremacy. His subjects were so generally indignant at these efforts that the King was driven from his throne (1688). It is calculated that at this time nineteen-twentieths of them were, at least nominally, adherents of the church. William and Mary were declared King and Queen. Hence arose the nonjurors—bishops and others who refused to swear allegiance to the new dynasty. The greatest among them were Ken and Sancroft. Much controversy ensued; but eventually most of the nonjurors returned to the church and were reconciled to the succession. Sheldon had perhaps greater and more uncontrolled power than any who had preceded or have followed him in the primacy. He superintended and to a large extent dictated the reconstruction of the churches of England, Scotland, and Wales, after the Great Rebellion.

With the formation, in 1698, of the Society for Promoting Christian Knowledge, in 1701, of the Society for the Propagation of the Gospel in Foreign Parts, and, in 1709, of the Society for the Relief of the Poor in London, the church began her history in the eighteenth century under most favorable circumstances. The clergy attained to an influence never before surpassed, their great zeal and disinterestedness contributing in no small measure to this result. The advent of George I boded no good to the church. Before long, Bishop Hoadley's heterodox writings brought much disquiet and harm. They were condemned by Convocation, for which act it was summarily prorogued—to reassemble, without legislative functions, only in the middle of the next century—the foreign prince's ministers treating the matter as one of a political character. How many evils resulted from the long-continued silence of the church's greatest council it is impossible to say, but it was a blow from which it took many years to recover. Walpole, who was so influential with the monarch, encouraged a policy of quietness, and, by practically preventing the discussion of abuses, became a very questionable benefactor to the church.

Various causes tended to prevent the fair prospects that marked the opening of the eighteenth century from being realized at its close. Prominent among these may be mentioned the system of pluralities and nonresidence and the abuse of patronage. The church was now somewhat in a transition state. Not being compelled any longer to fight for her very existence and nationality, her members fell—not unnaturally, perhaps—into something like lethargy. From this condition she was aroused in the middle of the century by such men of intellectual ability as Butler, Waterland, Berkeley, Warburton, and Conybeare, as also by the saintly life of Wilson, Bishop of Sodor and Man, and the devout writings of William Law. Tillotson, although be-

longing to the previous century, was still influential through his writings.

It is not necessary to trace the history, in this connection, of what is known as Methodism (q.v.), but it must be taken into consideration in forming a correct idea of the church's real condition at this period. While both John Wesley and his brother Charles never left the communion of their mother church, and uttered the most severe and solemn denunciations against any of their followers who should do so and should dare to set up a new organization outside of the church, yet doubtless they would have been more enthusiastic churchmen than they were (Charles was more consistent than John), had there been more sympathetic appreciation of their devout aspirations and unselfish labors.

What is known as the Evangelical school arose at the close of the eighteenth century and was a dominant factor in the church for a full generation. Some of its most famous adherents were Cecil, Venn, Milner, Newton, and Simeon. It met an undeniable want and contributed much to the advantage of the church. The Tractarian (sometimes called, from its source, the Oxford) movement—so named from the publication from 1833 to 1841 of a series of "Tracts for the Times"—did very much to arouse the latent energy of the church and to prepare her for availing herself of her great opportunities. Pusey, Keble, Newman, Williams, are names that stand for the restoration of a catholic faith not less essential to the church than the gospel truths which the others rightly magnified.

The remainder of the nineteenth century was filled with events of great interest and importance and with characters illustrious for their talents and virtues. It is completely covered by the reign of Queen Victoria. During the period there were constant heated controversies over such matters as the Catholic Emancipation Act (1827 and later), the disestablishment of the Irish church (which went into effect in 1871), the removal of disabilities from Jews and atheists, the *Essays and Reviews* (containing nothing particularly new, but attracting wide attention because of their distinguished authors), the Gorham Judgment (as to baptismal regeneration, the decision of Bishop Colenso for his views of the inspiration of Holy Scripture, the Public Worship Regulation Act (1874), the Lincoln Judgment (dealing with ceremonial acts in the celebration of Holy Communion, the unsuccessful attempts to disestablish the church in Wales, and religious education in the National Schools. The Royal Commission on Ecclesiastical Discipline, appointed in 1904, presented a unanimous report in July, 1906, recommending among other things modification of the law with a view to greater elasticity; reconstitution of the ecclesiastical courts, with abolition of bishop's veto on prosecutions, and an increase in the number of bishops.

In its missionary enterprises of all kinds, in its charitable and educational schemes, in the multiplication and endowment of new dioceses and parishes, and in the development of the spiritual side of its life, no period can show more zeal and liberality. With all this energy there would seem to be a growing charity among those that differ honestly from each other.

That there are these differences appears further from the existence not only of what are called the High and Low Church parties, but

also of what is known as the Broad Church party, the progenitor of which was Samuel Taylor Coleridge, and which has numbered among its members Julius Charles Hare, Whewell, Thirlwall, Arnold, Stanley, Maurice, Kingsley, and Robertson.

Other names—such as Samuel Wilberforce, Liddon, Palmer, Church, Christopher Wordsworth, Lightfoot, Stubbs, Bright, Westcott, Magee, Butler, Hook, Burgon, Neale—will recall men who, as prelates, preachers, scholars, and pastors, have been worthy of the best days of the church.

For such an organization as the Church of England there is an amazingly small amount of law. There is no formal document styled constitutions. Of canons—enacted at various periods, many of them before the year 1604—there are nearly 150. Parliament may, with the sanction of the sovereign, impose upon the church any law. Convocations (q.v.) are called for the purpose of discussing ecclesiastical matters and of advising the crown concerning them. Their discussions, no matter how influential, cannot directly eventuate in law. The diocesan conferences and synods (the former composed of elected clergymen and laymen, the latter of clergymen alone) may likewise take action binding upon the conscience. The houses of laymen seek to give counsel to the convocations in matters of practical importance. The Representative Church Council, created in 1905, consists of three houses, formed by members of the convocations and houses of laymen of the provinces of Canterbury and York. The functions of the Church Congress, a wholly unofficial body, are confined entirely to the consideration of ecclesiastical topics.

There are two archbishops (q.v.). The Archbishop of Canterbury, entitled Primate of All England, had under him, in 1914, 59 bishops, with 29 dioceses. The Archbishop of York had 18 bishops, with 10 dioceses. Next in dignity to the bishops are the deans and archdeacons (q.v.). Then follow canons, prebendaries, rectors, vicars, and curates. The right of presentation to parochial benefices is almost wholly in the hands of certain clerical or lay persons or bodies called "patrons" of the "living." (See PATRONAGE, ECCLESIASTICAL.) There are voluntary organizations, called church boards or parochial councils, who act as advisers and helpers to the clergymen and churchwardens. The vestry of each parish is a body whose membership and meetings are open to all ratepayers, and whose functions are largely civil. They have, among other things, the settlement of church rates, which are voluntary and cannot be recovered by law.

Because of the existence of large endowments, many of the churches are wholly or partially relieved of the necessity of contributing to the support of the clergy and are therefore the more free to give to other ecclesiastical objects. The income for general purposes in 1913 equaled £7,900,230. The principal items of receipts were: maintenance of church services, £1,628,356; church buildings, £1,119,289; foreign missions, £933,981; maintenance of assistant clergy, £863,802; home missions, £814,808; support of the poor, £455,659; philanthropic work, £609,010.

As to organized work, there would seem to have been but little, outside of the universities and schools, until the beginning of the eighteenth century. The Society for the Propagation of the

Gospel and the Church Missionary Society include in their operations almost all the heathen parts of Asia and Africa as well as all the colonies of Great Britain. Provision is regularly made, by means of temporary or resident chaplains, for services of the church in many towns and villages on the continent of Europe where English-speaking people are found in any considerable numbers.

In home-mission work the agencies are almost countless. The army, the navy, seamen, drunkards, fallen women, friendless girls and lads, the navvies, the hop pickers, the deaf, dumb, and blind, the Jews, the waifs and strays and uneducated—all these and many other classes are provided for by organizations more or less national in their character. There exist also orders of a semimonastic character composed of men, of women, or of both, by means of which much of the church's work is done. Sisterhoods (q.v.), of which a number have been formed, were first organized in the year 1845, under the direction of Dr. Pusey. In 1913 there were in all 14,019 benefices or cures and about 27,000 clergymen. See **ANGLICAN COMMUNION**; **REFORMATION**; **PRAYER BOOK, COMMON**; **BISHOP**; **TITHES**; **ESTABLISHMENTS, ECCLESIASTICAL**; **APOSTOLIC SUCCESSION**.

Haddan and Stubbs, *Councils and Ecclesiastical Documents* (Oxford, 1869-71); Bright, *Early English Church History* (ib., 1888); Dixon, *History of the Church of England, from the Abolition of the Roman Jurisdiction* (6 vols., London, 1877-1902); Hore, *The Church in England from William III to Victoria* (ib., 1886-88); Wakeman, *Introduction to the History of the Church of England* (ib., 1898); Overton, *The English Church in the Nineteenth Century* (New York, 1894); Stephens and Hunt, *History of the English Church* (9 vols., ib., 1900-10); Hutton, *The English Church, 1625-1714* (ib., 1903); Newbolt and Stone, *Church of England: An Appeal to Facts and Principles* (ib., 1903); Noyes, *Aspects of Anglicanism* (ib., 1906); Ollard and Crosse, *Dictionary of English Church History* (ib., 1913); various writers, *Church Historical Society Papers* (ib., 1895-1910); Worsley, *The Theology of the Church of England* (ib., 1913); and the *Official Year-Book of the Church of England*.

ENGLAND'S HELICON. An anthology of English poems, edited by John Bodenham in 1600 and reissued in 1812. It contains 150 poems by the leading writers of the day.

EN'GLEHEART, GEORGE (1752-1829). An English miniature painter. He was born at Kew and studied under George Barret and Sir Joshua Reynolds. He first exhibited at the Academy in 1773, and between that time and 1813, when he retired, he painted about 4853 miniatures. He usually painted on ivory, though sometimes he used enamel. His miniatures are careful in draftsmanship, good in color, and show fine power of characterization. In 1790 he was appointed miniature painter to King George III, whom he portrayed 25 times; and as most of the important personages of the court were numbered among his sitters, he entered into serious rivalry with the famous Richard Cosway. He also made miniature copies of many of Reynolds's paintings.—**JOHN COX DILLMAN ENGLEHEART** (1783-1862), his nephew and pupil, was also a popular miniature painter until ill health obliged him to retire from the profession in 1828. A fine collection of the works of both artists including

a miniature of George III, painted by himself, is in the J. P. Morgan . . . Metropolitan Museum, New York). Consult Williamson and Engleheart, *George Engleheart* (London, 1902). **EN'GLEMANN'S TUNA.** See **PRICKLY PEAR**.

ENGLER, ɛŋ'glər, EDMUND ARTHUR (1856-). An American educator, born in St. Louis, Mo. He was educated at Washington University (A.B., 1876; A.M., 1879; Ph.D., 1892), where he was professor of mathematics from 1881 to 1901, dean of the School of Engineering from 1896 to 1901, and secretary and treasurer of the university after 1911. Between 1901 and 1911 he was president of Worcester (Mass.) Polytechnic Institute. In 1889 he was a member of the Washington University eclipse expedition to Norman, Cal. He also served as chairman of juries of awards at the Buffalo Exposition in 1901 and at the St. Louis Exposition in 1904. From 1898 to 1901 and in 1912-13 he was president of the St. Louis Academy of Science. His publications consist of many scientific articles contributed to the magazines.

ENGLER, ɛŋ'glər, HEINRICH GUSTAV ADOLF (1844-). A German botanist, born at Sagan and educated at Breslau. He was professor of botany at the University of Kiel from 1878 to 1884, at Breslau from 1884 to 1889, and was appointed in 1889 to the same chair at Berlin, where he was also made director of the Botanical Gardens. His chief botanical interests came to be taxonomy (classification) and plant geography. In 1881 he became editor of the *Botanische Jahrbücher*, which is the leading periodical dealing with taxonomy, the history of plants, and plant geography. He initiated and carried forward successfully several extensive publications, viz., *Die natürlichen Pflanzenfamilien* (in collaboration with Prantl), a systematic presentation of all of the plant genera of the world; *Das Pflanzenreich*, a presentation of all of the species of the world; *Die Vegetation der Erde* (in collaboration with Drude), a detailed account of the plant geography of different regions of the world. Perhaps his most notable publication is the *Syllabus der Pflanzenfamilien*, in which there is a reorganization of the scheme of classification. This has been adopted almost universally, so that the "Engler sequence" obtains in almost all manuals of botany.

ENGLES, WILLIAM MORRISON (1797-1867). An American author, born in Philadelphia, Pa., and educated at the University of Pennsylvania. In 1818 he became a Presbyterian missionary in the Wyoming valley and, after holding a pastorate of 14 years in Philadelphia, in 1834 became editor of the *Presbyterian* and in 1838 editor for the Presbyterian Board of Publication, of which he became president in 1863. He was moderator of the Presbyterian General Assembly in 1840. His works include: *Records of the Presbyterian Church* (1840); *English Martyrology* (1843); and the *Sailors' Companion* (1857) and the *Soldiers' Pocketbook* (1861), which attained a circulation of 300,000, during the Civil War.

ENGLEWOOD, ɛŋ'g'l-wud. A city in Arapahoe Co., Colo., 6 miles south of Denver, with which it is connected by trolley. It is in an agricultural, dairying, and stock-raising region, and contains the National Swedish Sanitarium and the Molkeray Sanitarium. There are also many fine homes. Pop., 1910, 2983.

ENGLEWOOD. A city in Bergen Co., N. J., 14 miles by rail north of Jersey City on the

Erie Railroad (Map: New Jersey, E 2). It lies on the gentle western declivity of the Palisades of the Hudson, and is purely residential. The city contains a hospital and a public library. The township of Englewood was set off from the old township of Hackensack in 1871. Englewood was incorporated as a city in 1895, but the act of incorporation was declared unconstitutional and it was reincorporated in 1899. Pop., 1900, 6253; 1910, 9924; 1914 (U. S. est.), 11,487.

ENGLISCH, *ëng'lish*, JOSEPH (1835-). An Austrian surgeon, born at Freudenthal, Austrian Silesia, and educated at the University of Vienna. In 1871 he became one of the physicians in chief at the Rudoliftstiftung, Vienna, and in 1892 was made professor of surgery at the Vienna University. He became a distinguished authority on genitourinary diseases. Among his numerous publications on rupture, genitourinary diseases, malformation of the sexual organs, and cognate subjects, are: *Ueber Ovarialkernien* (1871); *Zur Radikalbehandlung der Eingeweidebrüche* (1878); *Ueber abnorme Lagerung des Hodens ausserhalb der Bauchhöhle* (1885); *Ueber angeborene Penisfisteln* (1892).

ENGLISH, GEORGE BETHUNE (1787-1828). An American author and adventurer. He was born at Cambridge, Mass., graduated at Harvard, became a member of the Boston bar, and studied theology. He soon began to doubt the truth of Christianity, however, and published in 1813 *The Grounds of Christianity Examined*, a work favoring Judaism, which called out Edward Everett's *Defence of Christianity* (1814). He subsequently edited a paper in the West and then served in the Mediterranean as a lieutenant of marines. In 1820 he resigned his commission to serve under Ismail Pasha in Egypt, and won distinction as an officer of artillery in the expedition against Sennar. He was subsequently agent for the United States government in the Levant, but returned home in 1827. He published *Narrative of the Expedition to Dongola and Sennaar* (1822).

ENGLISH, THOMAS DUNN (1819-1902). An American physician and man of letters, born in Philadelphia, Pa. English, whose family name is a corruption of Angelos, studied medicine in his native city, and graduated at the University of Pennsylvania Medical School in 1839. He speedily gave up the practice of medicine for law, however, and was admitted to the Philadelphia bar in 1842. In 1844 he embarked in journalism in New York and in 1845 established the *Aristidean*. After 1859 he practiced medicine at Newark, N. J. A Democrat in politics, he was a member of the New Jersey Legislature in 1863-64 and represented his district for two terms (1891-95) in the United States House of Representatives. He also gave much attention to literature, aside from being a magazine editor and journalist. The following are the principal titles of his works, chiefly novels and poems: *Zephaniah Doolittle* (1838); *Walter Woolfe* (1842); *MDCCCXLIV: or, The Power of the "S. F."* (1847), a semipolitical novel; *Poems* (1855); *Ambrose l'ecit: or, The Peer and the Printer* (1869); *American Ballads* (1882); *Boy's Book of Battle Lyrics* (1885); *Jacob Schuyler's Millions* (1886); *Select Poems* (1894), ed. by his daughter; *Fairy Stories and Wonder Tales* (1897); *The Little Giant, The Big Dwarf, and Two Other Wonder-Tales* (1904). He is popularly known by the song "Ben Bolt," published

in Willis's *New York Mirror* in 1843 and never highly ranked by him among his poems. As set to music by Nelson Kneass, this became widely popular in both England and America and after a temporary obscurity was later revived through its introduction by Du Maurier into the novel *Trilby* (1894). "The Gallows Goers," treating of capital punishment, also had wide circulation.

ENGLISH, WILLIAM HAYDEN (1822-96). An American politician. He was born at Lexington, Ind.; studied law, and in 1843 was chosen clerk of the Indiana House of Representatives. He was secretary of the State Constitutional Convention which framed the Constitution of 1850, and in the following year was made Speaker of the House under the new Constitution. From 1853 until 1861, when he retired from active political life, he was a Democratic member of the Federal House of Representatives. His chief title to distinction was his unanimous nomination for the Vice-Presidency of the United States by the Democratic National Convention, in 1880, on the ticket with Gen. Winfield S. Hancock. He is author of the congressional measure relative to the admission of Kansas as a State, known as the English Bill. He published *The Conquest of the Country Northwest of the River Ohio, 1778-83, and Life of George Rogers Clark* (2 vols., 1896)—a somewhat uncritical work which, however, contains a mass of valuable material. Consult Keyser, *The Life of William H. English, the Democratic Candidate for Vice-President of the United States* (Philadelphia, 1880).

ENGLISH CHANNEL (Fr. *La Manche*, the sleeve). A reach of the North Atlantic Ocean separating England from France, and commonly called THE CHANNEL, the most important marine thoroughfare in the world (Map: Europe, C 3). It is connected with the North Sea by the Strait of Dover, 20 miles wide at its narrowest point. From this strait it extends west-southwest for 280 miles, and joins the Atlantic Ocean at the Chops, between the Scilly Isles and Ushant Isle, where the breadth is 100 miles. The average breadth is 70 miles; the greatest breadth is 140 miles—from Sidmouth to Saint-Malo. The average depth of the eastern half reaches about 200 feet; at the Strait of Dover the depth varies from 6 to 120 feet, while in the western half the depth averages about 300 feet, and in places even exceeds 500 feet. A coarse gravel covers the bottom. The Channel occupies about 30,000 square miles, and contains the Scilly Isles, Channel Islands, Isle of Wight, Ushant Isle, and many islets and rocks, especially off the coast of Brittany. The Seine is the largest river which flows into it. Pilchard, mackerel, and other fish, as well as oysters, abound. The English coast line, extending from Dover to Land's End, is 390 miles long, and the French, extending from Calais to Ushant, 570 miles. The chief English seaports on the Channel are Falmouth, Plymouth, Southampton, Portsmouth, Brighton, Folkestone, and Dover; the chief French ports are Cherbourg, Havre, Dieppe, Boulogne, and Calais. High tides, with a rise of from 37 to 42 feet, prevail on the south shore. The phenomenon of double high water is seen between Poole and Southampton, the tide coming in first by the Solent, and again by Spithead three hours later. The sea is generally rough and unpleasant for travel, owing to the contrary currents. Plans for making a

continuous connection between London and Paris across the Channel have been numerous; the most common include tunneling, bridging, and running train ferries. The last tunnel project, in 1907, was opposed by the government. The *Oceanus Britannicus* of the Romans, the Channel has been the scene of many important historical events, including the destruction of the Spanish Armada, the battle of La Hogue, the fight between the *Kearsarge* and the *Alabama*, etc.

ENGLISH CONSTITUTION. See PARLIAMENT.

ENGLISH DIALECTS. See ENGLISH LANGUAGE; SCOTTISH LANGUAGE AND LITERATURE.

ENGLISHERY, or ENGLSCHERIE. The fact of being an Englishman, and not a Dane. The term refers to the curious exemption of a community in which an Englishman was found secretly slain, from the burden of making satisfaction for the murder. This ancient principle of the liability of the family, or mark, for the deeds of violence of its members is said by early English writers to have been introduced into England by Canute, the Dane (1015 A.D.). Probably it had long existed, and had become nearly obsolete by his time, but was revived by him as a measure for the protection of his own followers from native violence. The community indicted of the crime might make a "presentment of Englishery"—i.e., might set up a formal plea that the victim of the crime was an Englishman; which being established to the satisfaction of the court, the matter was left to the local law and the community was discharged of its indictment. The practice was maintained for many years after the reason for it had passed away, and it was not till the twenty-first year of Edward III (1348) that presentment of Englishery was abolished by act of Parliament. Consult Stephen, *History of the Criminal Law of England* (London, 1883).

ENGLISH HARBOR. An important harbor on the south coast of Antigua, West Indies, one mile from Falmouth. It is the site of a British naval station, and has a good harbor.

ENGLISH HORN. The cor anglais (q.v.). See Plate of MUSICAL INSTRUMENTS.

ENGLISH LAND. See ENGLISH PALE.

ENGLISH LANGUAGE. The chief medium of communication in the British Empire and the United States. It is the language used originally by the Teutonic tribes that invaded the island of Britain during the latter half of the fifth century. It belongs historically to the western branch of the Teutonic languages (q.v.) and to the Low German subdivision of that branch, being most closely allied to the Frisian (q.v.). In spite of the composite character of its vocabulary, less than one-third of which is native, modern English is still an essentially Germanic language—the real nature of a language is determined not by its vocabulary, but by its grammatical structure. The grammatical forms of English, its verbal system, the declension of its nouns and pronouns, the comparison of its adjectives and most of its purely relational words, such as simple adverbs, prepositions, and conjunctions, are native. All the numerals, too, except *second* and those above a thousand, have always been in the language. The changes that have taken place in English grammar have been due to the leveling of old inflections, not to the introduction of new ones.

In tracing the growth of the English language, the history is usually divided into three leading periods: The Old English period (449 A.D. to 1100 A.D.), the Middle English (1100–1500), and the Modern English period (1500 to the present time). But the name of the first period is now criticized by an increasing number of scholars, who affirm, not that English was always English, and never Anglo-Saxon; that the fact that it was inflected in the period before the Norman Conquest, and lost most of its inflections in later times, is no reason for speaking of it as if it were two different languages; and that we have no warrant in the usage of the inflected period for calling our forefathers or their speech anything but English. The term Anglo-Saxon did not come into use until in the seventeenth century, at the time of the revival of an interest in our earliest literature, so that the word is not only misleading, but has not even the merit of antiquity. The term Old English, furthermore, is in keeping with the classification of the other Germanic languages. But as the term Anglo-Saxon has been so long in common use and is clearly understood by all readers, whereas the more exact term Old English is sometimes incorrectly applied to later periods, possible confusion is avoided by retaining the first.

As early as the fifth century, Teutonic invaders from the Continent settled in Britain and drove the original Celtic-speaking inhabitants to the north and west of the island; so that before the battle of Hastings (1066) the tongue of the conquerors had been spoken in England for at least six hundred years. The final absorption, after numerous conflicts, by the kings of Wessex, or of the West Saxons, of the various states of the "Heptarchy," in the ninth century, went far to make the ruling speech of the land identical with that of Berkshire and Hants, the recognized centre of the predominant sept. The use, besides, of this southern speech as the chief instrument of literary communication was permanently confirmed by the influence of King Alfred, a native of Berks. Few existing monuments of the language remain that permit us to go further back than the time of this literary monarch; yet, from the writings of Cædmon, who was a North-Anglian, and a few ecclesiastical manuscripts from the Kingdom of Northumbria, which extended from the Humber to the Firth of Forth, it has been generally concluded that at least two principal dialects must have been used in the island—a northern, including Mercian and Northumbrian, and a southern, including Kentish and West Saxon. The northern, or Anglian, was to some extent marked by Scandinavian features. This is not at all surprising if we admit that the Angles came from that corner of Schleswig still called Angeln, or indeed from any region north of the Elbe, aside from the influence of the Danes. It should be noted, too, that many works that are known to us in a West Saxon form were originally written in Northumbrian, as *Bœowulf* and Bede's translation of the *Ecclesiastical History of Britain*. It was the custom of mediæval scribes to use their own dialect in copying works from another.

It is important to notice here that neither the Anglian nor the Saxon borrowed much from the language of the conquered Britons. The largest single class of Celtic words in Anglo-Saxon is in connection with geographical names, such as

Aberdeen, mouth of the Dee, *Inchcape*, island cape, and *kill*, meaning church, in *Kildare*. Only 10 common nouns borrowed from Celtic in Anglo-Saxon are given by Skeat (*Principles of English Etymology*), among these being *bannock*, *cart*, *down*, *mattock*. It is possible, however, that other Celtic words were in use that have not been preserved in literature; but most of those of Welsh, Gaelic, or Irish origin that are found in modern English are comparatively recent borrowings. Very few, in fact, go back as far as the Middle English period. A few Latin words were evidently introduced through the Celtic. Some of these are geographical names, having different forms of the word *castra*, camp, as the last part; among the others may be noted *lake*, *mount*, *street*, *wine*. A few Latin words were brought to Britain from the Continent, where the Teutons had already come into contact with Roman culture. It may be inferred that all Latin derivatives found in Anglo-Saxon and in other early Germanic languages are preinsular. Among these have been suggested *chalk*, *coulter*, *mint*. But by far the largest borrowing of Latin words during the Anglo-Saxon period came as a result of the introduction of Christianity in Kent in 597. Not only ecclesiastical words directly connected with the new faith, but many general words found their way into the language. The total number of Latin words introduced at this time is estimated by Skeat at 140. From among these may be taken the following examples: *altar*, *mass*, *priest*, *psalm*, *temple*, *kitchen*, *palm*, *pear*, *tunic*. It should be noted that several of these words are of Greek origin. Not a few Scandinavian words were borrowed, mainly as a result of the Danish invasions. Several of these occur for the first time in the accounts of the engagements between the English and the Danes given in the *Anglo-Saxon Chronicle*. Thus *earl*, first applied only to Danish leaders, later took the place of the English *alderman*. Other words are *husband*, *knife*, *take*, *window*. Great difficulty is often experienced in determining the Scandinavian element in Anglo-Saxon, owing to the close resemblance between Northumbrian and Norse.

The early part of the Middle English period, sometimes called Semi-Saxon, is a period of transition, and, like every transition era, it is marked by confusion. The absence of any recognized standard dialect added greatly to the confusion. The monks of the time, accustomed to the use of mediæval Latin, had in a great measure forgotten the grammar of their native language and, when they attempted to write it, did so very badly. The *Chronicle*, which in its latest forms comes down to 1154, and Layamon's *Brut*, written about 1190 or 1200, exhibit traces of the breaking up of the grammar. During the Middle English period all the important changes took place that resulted in transforming English from a highly inflected into a practically uninflected language. It should be remembered, however, that the tendency of English to substitute an analytical for a synthetical structure, i.e., to indicate syntactical relations by the use of particles and by the . . . in the sentence, is not peculiar to our language. Among the Scandinavian languages, Danish and Swedish belong now to about the same stage as English, and Dutch is no less distinctly analytical. German, on the other hand, is still a highly inflected language. Beginning with the noun in English, we find that as early as 1200 the three or four

cases in the singular had been reduced to two in the majority of nouns, and that in the plural the common form in *es* had been adopted. During the latter part of the period almost all nouns were declined in practically their present manner. The apostrophe in the genitive singular was introduced to indicate the original *e* of the ending, and it was later extended to the plural. The simplification of the declension of the noun was effected by two principles—one phonetic, the weakening of all the vowels of the endings to *e* and the dropping of final *n*, which reduced all vowel endings to the one form; the other logical, the principle of analogy, by which the various declensions of Anglo-Saxon were reduced to the most prominent one, the strong masculine ending in the plural in *as*, later weakened to *es*. Only one original weak plural, *oxen*, has survived in Modern English, *kine* and *brethren* being later formations. Several representatives of the so-called mutation class, or nouns showing a modification of the root vowel in the plural, as *man*, *men*, *foot*, *feet*, are still found, and there are also a few nouns having the same form in the plural as in the singular, as *deer*, survivals of Anglo-Saxon neuters. Along with the leveling of inflections there has been a change from the grammatical to the natural gender. This was a necessary result of the loss of distinctive inflectional endings. In the adjective there has been a complete loss of inflections, since comparison belongs, not to inflection, but to composition. In this respect English has gone further than Danish, in which a distinctive form has been retained for the definite and the plural. The definite form of the adjective is still used by Chaucer. In the declension of the pronoun the dual number has been lost, and the dative and accusative have been reduced to a common form, derived in most instances from the dative. One entirely new form, *its*, has been developed in the seventeenth century, the original genitive being *his*, which is the only form used in the King James translation of the Bible. The relatives *who*, *which*, *that*, were introduced in the Middle English period, and the plural of the demonstrative *they* was substituted for the original plural *hi* of the third personal pronoun. In the conjugation of the verb the principal change has been in the loss of about two-thirds of the strong class, most of them passing over to the weak conjugation. With a very few exceptions all verbs borrowed from foreign languages during the Middle and Modern periods are weak. This tendency is the result of analogy. The conjugation has also been greatly simplified by the loss of endings and the use of a common form for the singular and plural of strong verbs.

It will be seen from this brief survey that Modern English, although it has greatly simplified its inflection, is not a wholly analytical language. In the nouns the process has been carried further than in the pronouns, since in the former the relation of subject and object is determined wholly by position, while in the latter there is in most cases a distinct form for each. That there is a tendency, especially in the speech of the uneducated, to disregard this distinction in the pronoun is clearly shown by such idioms as "Who are you talking to?" "between you and I." The solecisms, "you was," "they was," indicate a similar tendency in the verb.

Turning now to the foreign element in the vocabulary of Middle and Modern English, we should take care to distinguish between the Nor-

man French words introduced during the former, and the Parisian or standard French words introduced during the latter, period. As Skeat truly states (*Principles of English Etymology*, part ii): "Hundreds of words of Anglo-French origin, owing to their early introduction into the language, and the thoroughness with which they have been incorporated in it, have quite as strong a claim to our attention, and are found in practice to be quite as useful in their way as are those of truly native origin." (See NORMAN-FRENCH.) The presence of French is very noticeable in the poetry of Chaucer and Gower; but there is no ground for the statement that these writers corrupted the language by a large admixture of novel French words.

We may here notice the question which has often been asked: "Which of the early dialects spoken in England is the origin of the form now used?" We have seen that in the Anglo-Saxon period two were used for literary purposes—a Northern, or Anglian, and a Southern, or Saxon. In the period, however, succeeding the Norman Conquest, and more especially after 1250, we find not two, but three dialects: a Northern, a Midland, and a Southern. During the fourteenth century circumstances gave prominence to the Midland counties, in which arose the great universities, the rich monasteries, and many other religious foundations. One of its subdivisions, the East Midland, was the dialect in which Wiclif, Gower, and, above all, Chaucer wrote. It had then become the speech of the metropolis and had probably forced its way south of the Thames into Kent and Surrey. All these circumstances, combined with the fact that the Midland avoided the extremes of the Northern on the one hand and of the Southern on the other—that it was, in fact, a sort of compromise—gave to the East Midland a commanding position and made it the parent of the Modern English literary language. But while the East Midland came to be regarded as the standard English speech, the other dialects continued to exist and are in use at the present day; and a nucleus of new dialects, based upon several of the parent dialects, but gradually departing from them, has developed in the United States. (See AMERICANISMS.) Although all Anglo-Saxons write practically the same form of English, in their everyday speech they show differences of pronunciation and of vocabulary that are very marked. In English there is no standard of pronunciation such as is given in French by the French Academy.

During the Modern period of English the most decided change in the language has been in connection with the vocabulary. Ever since the beginning of this period the language has borrowed freely from many foreign sources. As a result of the influence of the Italian Renaissance at the beginning of the sixteenth century, many Italian words were introduced, and in spite of Ascham's dislike of them they increased rapidly. Contact with Spain on the Western Continent led to the borrowing of many Spanish words, and the commercial relations with Holland are responsible for the introduction of not a few Dutch words, especially maritime terms. In the seventeenth century political and literary connections with France helped to augment the French element, which has become extremely abundant, and the advances of science have created an immense number of classical terms, either borrowed or formed from the Latin and

Greek. Wherever Englishmen have gone they have absorbed into their language words describing local objects and ideas. The British conquest of India has brought in such words as *bangle*, *chintz*, *loot*, *mahout*; the war in South Africa has Anglicized some Dutch words, as *trek*, *outlander*; commercial relations with China have given Chinese words, as *china* and the names for the different kinds of tea. Of especial interest is the large class of Indian words, brought from North and South America, borrowed either directly or through the Spanish or Portuguese. Many of these come under the head of "Americanisms." During the four centuries of the Modern period the English vocabulary has gradually assumed the composite character which is one of its most striking features. All the Germanic languages, indeed, show a marked tendency to assimilate foreign words. The only point of inferiority that the modern English vocabulary shows as compared with the vocabulary of the oldest period is in the power to form self-explaining compounds, in which Anglo-Saxon was as rich as modern German. This inferiority of modern English is not so great, however, as would appear, since many words that are really compounds are written as separate words, as *insurance company*, *life insurance*. Many writers have at different times deplored the cosmopolitan character of the English vocabulary and have urged the exclusive use of native words in all possible cases. This extreme purism, however, ignores entirely the value of a varied vocabulary for purposes of literary expression, without which the language of Shakespeare and Milton would lack much of its beauty and force. The wise man selects from this rich treasury of words those that best express his thoughts.

Bibliography. ANGLO-SAXON: Bosworth-Toller, *An Anglo-Saxon Dictionary* (Oxford, 1882-98), the only complete recent work of the kind; Sweet, *The Student's Dictionary of Anglo-Saxon* (ib., 1897), a convenient list, but without references; id., *An Anglo-Saxon Reader* (ib., 1876-79; 8th ed., London, 1908); Bright, *An Anglo-Saxon Reader* (3d ed., New York, 1894); Sievers, *An Old English Grammar*, trans. by Cook (3d ed., Boston, 1903); J. and E. M. Wright, *Old English Grammar* (London, 1908); Bodtker, *Critical Contributions to Early English Syntax* (Christiania, 1908-10); Sweet, *An Anglo-Saxon Primer* (Oxford, 1900); March, *A Comparative Grammar of the Anglo-Saxon Language* (New York, 1875), still useful for the syntax; Sweet, *A Second Anglo-Saxon Reader* (Oxford, 1887), contains archaic and dialectic texts; Grein, Holthausen, and Köhler, *Sprachschatz der angelsächsischen Dichter* (Heidelberg, 1912), containing a fund of material. Callaway, *The Infinitive in Anglo-Saxon* (Washington, 1913), is an important technical contribution.

MIDDLE ENGLISH: Stratmann, *A Dictionary of the Middle English Language*, rev. by Bradley (Oxford, 1891); Mayhew and Skeat, *A Concise Dictionary of Middle English from 1150 to 1580* (ib., 1888); Sweet, *First Middle English Primer*, with grammar and glossary (ib., 1884); *Second Middle English Primer, Extracts from Chaucer* (1886); O. F. Emerson, *Middle English Reader* (New York, 1905); Morris, *Specimens of Early English 1150-1300* (Oxford, 1886); Morris and Skeat, *Specimens of Early English, 1298-1394* (ib., 1886); Skeat, *The Vision of . . . Piers the Plowman*, by William Langland (ib., 1867-73).

SHAKESPEARE: Abbott, *A Shakespearean Gram-*

mar (London, 1870), an excellent treatment; Schmidt, *Shakespeare-Lexicon* (3d ed., Berlin and London, 1902).

HISTORY AND GRAMMAR: Skeat, *Principles of English Etymology*, two parts (London, 1887 and 1891), treats the native and foreign elements separately and, although not always in agreement with the latest results of philological investigation, is nevertheless an excellent introduction for the general student; Skeat, *The Science of English* (Oxford, 1912), is a very useful manual; Iorp's ed. of Fick and Falk's *Wortschatz der germanischen Spracheinheit* (Göttingen, 1909) and Skeat's *Etymological Dictionary of the English Language* (new ed., Oxford, 1910) are noteworthy; Emerson, *The History of the English Language* (New York, 1894), the most scientific textbook on the subject; Morris, *Organic History of English Words* (Strassburg, 1909); Mitchell, *Significant Etymology* (London, 1908); *Outline History of the English Language* (New York, 1906) is a more elementary work; Lounsbury, *History of the English Language*, rev. ed. (New York, 1894), a well-considered book, but with slight treatment of the phonetic side; Toller, *Outlines of the History of the English Language* (New York, 1900), connecting the development of the language with the literature. Other useful works are Krapp's *Modern English, its Growth and Present Use* (New York, 1909) and Lindelöf, *Grundzüge der Geschichte der englischen Sprache* (Leipzig, 1912). A technical treatment of the history of the language is given by Kluge in Paul, *Grundriss der germanischen Philologie* (Strassburg, 1910); Morris, *Historical Outlines of English Accidence* (London, 1872); Kellner, *Historical Outlines of English Syntax* (New York, 1892), a useful introduction to the study of the subject; Jespersen, *Progress in Language* (London, 1894), containing a suggestive study of the English pronoun; id., *Growth and Structure of the English Language* (Leipzig, 1905); id., *Modern English Grammar on Historical Principles* (2 vols., Heidelberg, 1909-14); Kaluza, *Historische Grammatik der englischen Sprache* (2d ed., 2 vols., Berlin, 1906-07); Sweet, *A Short Historical English Grammar* (New York, 1892), a condensed treatment of phonology and accidence; id., *A New English Grammar, Logical and Historical* (ib., 1892 and 1898), vol. i containing phonology and accidence, and vol. ii syntax, this being an admirable treatment from the historical point of view; Bain, *A Higher English Grammar* (London, 1879), containing the earliest use of logical analysis, and in its treatment of the parts of speech making a distinct advance; Lees, *English Grammar on Historical Principles* (3d ed., London, 1906); Kittredge and Farley, *Advanced English Grammar* (Boston, 1913); Horn, *Historische Grammatik* (Strassburg, 1908); *English Grammar*, 1634, ed. by A. Eichler (Halle, 1910); *Sir Thomas Smith's De Recta et Emendata Linguae Anglicae Scriptione Dialogus*, 1568, ed. by Derbel (ib., 1913); Wright, *English Dialect Grammar* (Oxford, 1906); id., *English Dialect Dictionary* (New York, 1898-1906). Other works to be noted are: Lounsbury, *English Spelling and Spelling Reform* (ib., 1909); Schnaar, *Die englische Orthographie seit Shakespeare* (Marburg, 1907); Althaus, *Sounds of the Mother Tongue* (London, 1912); Michaelis and Jones, *Phonetic Dictionary of the English Language*

(Hanover, 1913); Pierce, *Dictionary of Hard Words* (New York, 1910); Spira, *Die englische Lautentwicklung nach französischen Grammatikerzeugnissen* (Strassburg, 1912); Derocquigny, *Contributions to the Study of the French Element in English* (Lille, 1904); Bastide, *De Recentiore Gallicorum Verborum Usu in Anglica Lingua* (Paris, 1906); Heck, *Beiträge zur Wortgeschichte der Englischen* (Halle, 1906). For an account of dictionaries of the modern period, see DICTIONARY.

ENGLISH LITERATURE. The literature produced by the English people, amid the varied course of their national development, and in the vernacular tongue, whether purely Teutonic, or the fusion of that element with the Norman-French, or the splendid and highly organized language, rich in its double inheritance, which modern times have raised to such a pitch of power, flexibility, and grace. It must be treated as substantially one under all these various aspects, though its beginnings are to its present maturity as the weakness of an infant to the rich endowment of a full-grown man. On the other hand, for convenience, if for no radical or logical distinction, the literature produced in practically the same language by daughter peoples across the seas will not come into this survey. Nor will the method of treatment followed here allow anything like a complete enumeration of the authors who have adorned one period or another; it is considered, for the present purpose, of far greater importance to show tendencies and trace the outline of gradual development. Upon this principle, consequently, not upon any attempt at appraisal of absolute values, will be based the proportion of space allotted to the writers for a discussion of whose work there is room. We need not consider here the songs of the British bards, whose race and language were driven into the outlying hill countries by the Teutonic invasion, and who, save in the one notable instance of their contribution to the Arthurian legend, gave practically nothing to the literature now under discussion. By the terms of our definition we are also dispensed from dwelling on the work produced in Latin, the common language of scholars, before and after the Norman Conquest.

The development of early English poetry on its external side was not unlike that of corresponding poetry elsewhere. It was the one intellectual amusement of a race of hardy fighters and hunters. They gathered in the long winter evenings about the fire, to listen to tales of the adventures which had come to other men like themselves. As on the Continent, there were two classes of singers—the *scōp*, the real poet (maker, French *trouvère*), who took the raw material of history or legend and shaped it into more or less artistic form; and the *gléoman*, who, like the Greek rhapsodist or the French *jongleur*, simply sang from place to place what he had learned from others. From these lays sprang the most important relic of the poetry of the pagan period, the epic of *Bēowulf*, which, although the only extant manuscript is of the tenth century, goes back for its inspiration and its subject to the sixth, and is therefore continental in its origin. It is impressive in its movement and imagery and possesses the dignity, if not the fullness, of the epic. Three other fragments from this period are of considerable interest—*Widsith*, or the Wanderer, probably

the oldest of all; *Waldhere*; and *The Fight at Finnsburg*. The characteristic of this early verse is its sombre grimness, and its picture of a life of constant combat, either with savage human foes or with nature in its sterner aspects, overshadowed by the approach of inevitable destiny.

But this fierce and gloomy tone was modified by the introduction of the gentler spirit of Christianity from Rome and from Ireland. The poetry written under this new influence, whose remains cluster about the ill-defined personalities of Cædmon and Cynewulf, finds a reason for a more cheerful view of life in the replacing of Fate by an all-loving and merciful Father. For its subjects it turns now to the legends of the saints; though even in these, as in *Judith*, e.g., the old savage joy in "goodly fight" still comes out. A few short poems of a lyrical or lyric-dramatic nature are of still wider interest, as connecting the work of these early singers definitely with the far-away Tennyson and Shelley. The tenderness and grace of *The Lover's Message* and *The Wanderer* remind us to take account of an imponderable but real admixture of Celtic elements in the people from whom they proceeded.

Prose grew up under Alfred (848-900) after he had set up a bulwark against barbarian invasion. Like most early prose, it is written for practical purposes—to convey instruction either in the truths of religion or in the facts of history. He translated from Latin the treatise of Boethius, *On the Consolation of Philosophy*, one of the favorite philo-sophical works of the Middle Ages; the Venerable Bede's *Ecclesiastical History*, the best historical work that England had yet produced; the *History of the World*, by Orosius, then considered a standard authority; and the *Pastoral Care* of St. Gregory the Great. More important still is the expansion under his direction of the meagre records of the monasteries into a clear and connected narrative, the *Anglo-Saxon Chronicle*, which continued without a break for two generations after the Conquest. The name of Ælfric (c.950-1021) must be mentioned as that of a man who showed signs of a real literary spirit in the sermons, which are his principal work. But the narrow and somewhat monotonous feeling of the Anglo-Saxon race could not have continued to evolve into a really great literature without precisely such an admixture of other elements as was to follow the Conquest and the resultant fusion of the two nationalities.

While the process was going on, classical and theological learning made considerable progress. Monasteries were busy, and the English universities had begun to crystallize around their original small nucleus. Lanfranc (1005-89) and Anselm (1033-1109), Alexander of Hales (?-1245) and Duns Scotus (?1265-1308), attained eminence in speculative philosophy; but they wrote in Latin, as did the historians of the same period, of whom the chief were William of Malmesbury (1090-1143), Geoffrey of Monmouth (?1100-1154), Giraldus Cambrensis (?1146-1120), and Matthew of Paris (?1200-59). The English tongue was undergoing such serious grammatical and phonetic changes as to unfit it for a vehicle of literary expression. The first indication of a living English literature appears in Layamon's *Brut* just after 1200. Influenced by the mass of French romance, he essayed for the first time to give his own language something

of the same character, and his position in the development of the Arthurian legend is of no small importance. After he had shown the way, numbers of English romances appeared, mostly translated or adapted from the French, though one of the most charming, *Sir Gawayne and the Green Knight*, is of native workmanship.

Besides the necessary delay in the interfusion of the two languages, there was also a question for the poets to settle as to which of two widely different verse forms should prevail. Saxon poetry had been based upon alliteration and accent; with its varying length of line, it was loose and flexible in structure. The French verse, on the other hand, depended for its effect upon rhyme and upon uniform line length and was thus exact and measured. The latter finally prevailed, after a period of great confusion; alliteration, as a rule, was dropped, to be used later only as an occasional ornament by masters of effect like Swinburne; while accent could no longer wander at will when the French prosody kept watch over it.

By the time that the language and its literary forms had accomplished their union, the life of the people also had completed a similar process. It was no longer Saxon here and Norman there, but was beginning to stand out as a new, independent, and finely molded nationality. Fortunately a great poet was ready to seize and fix on a broad canvas the varying hues of this full and brilliant life. Characteristically Chaucer (1340-1400) began by going to school to the French *trouvères* and to the later allegorical school of which the epoch-making *Roman de la Rose* is the typical work; then he went to Italy, where the sun of the Renaissance, not yet risen in England, was already calling to life manifold forms of intellectual and artistic activity; Dante, Petrarch, and Boccaccio stimulated him to rival their own productions and taught him to venerate the great masters of the classical ages. But his French and Italian periods were only periods of apprenticeship. When he had learned his trade, he threw aside imitation and stood forth boldly as an English poet—a finished artist in technical niceties as well as a great creator, who gave the final touch to the various literary forms which he found in cultivation, and drew from his ripe knowledge of men and things the power to stir the springs both of laughter and of tears as no one had done before him.

Chaucer and Gower (1325-1408) represent life from the aristocratic point of view, the former writing as an easy-going courtier, who simply ignores social questions, while the latter is conscious of their insurgence and stands stoutly for the old order against all tentative reforms. The other great names of the fourteenth century speak for the people and to the people. Langland—from whom analytical criticism has taken a part of *Piers Plowman*, long attributed to him alone—is of them; as he lies on the fair green expanse of Malvern Hills in the calm May sunshine, his heart is full of the paradoxes, the injustice, the unhappiness of the time, and he reasons out, through successive continuations and recastings of his work, a panacea for the ills of his generation. This, like the work of Wiclif (c.1320-84), is in the main religious. In an age when so many things conspired to make the life of the common people hard—taxation by the government for the endless drain of the French wars, oppression by the land-

lords, pestilence, storm—men's minds turned inevitably to the consolation of a world where inequalities should be redressed and sorrows comforted. The vision shines more and more clearly upon Langland's sight the more he ponders: Piers Plowman rises from a simple, honest tiller of the soil until he takes on the very lineaments of the incarnate Conqueror of death and hell. His thought has in many aspects a peculiarly modern tone—it is Carlyle who will take it up and reecho it—but in the structure of his verse he clings to the old rough alliterative form of the native English poetry, which, while it no doubt made a more direct appeal to his popular audience at the moment, unfitted him to have an influence upon the development of later poetry, now definitely committed through Chaucer to the assimilation of French forms. Wiclif, though the movement which we connect with his name was a university movement, appealed in the same way directly to the masses. This is not the place to discuss the effect or the justice of his crusade against the ecclesiastical system of his time; but by his translation of the Bible into the tongue of the plain people, and by the tracts which he wrote in homely, vigorous English, he affected in no small degree the development of the language. His Bible, in the various stages of its revision, exemplifies the final crystallization of a really English style, which at the same time, by its wide currency, it did more than any other book to fix and render uniform.

From this period until the Renaissance had tardily begun its work in England, there was little creative or really significant work. Lydgate and Occleve and James I of Scotland (the source of whose education entitles us to include him among English poets) were content to catch the trick of Chaucer's style and to name him and Gower as their avowed masters. Prose, however, in this as in all literatures later in its development than verse, began to take shape which is worthy of more than a passing notice. Though the universal employment of Latin as the language of scholars discouraged attempts to write serious English prose, yet the appeal of Wiclif's pamphlets and Reginald Pecock's *Repressor of Overmuch Blaming of the Clergy* to a popular audience brought it into the controversies of the time; and in lighter literature the *Voiage and Travaile of Sir John Maundeville* showed what could be done with it. This lesson was learned by Sir Thomas Malory, a greater master of style than the anonymous translator of that marvelous traveler's tale. The rhythm of his prose is at once stately and beautiful, simple and natural; and his *Morte d'Arthur* is the happiest thing in the whole of English fifteenth-century literature. That book, which Caxton printed in 1485, is intrinsically of high literary quality and is memorable, too, for the place it holds in the history of English fiction and for its long and potent influence upon English poetry to Tennyson and beyond.

In that very year Henry VII came to the throne, and the country, so long distracted by internecine warfare, had rest and leisure to think of intellectual culture. At last the "new learning" crossed the Channel and found a home in England. Grocyn (?1446-1519) and Linacre (?1460-1524) and their fellows were busy with their Greek manuscripts. Erasmus, the greatest scholar of the time, came to England, and with Colet (c.1467-1519) and More (1478-1535) dis-

cussed the great problems of church and state in a temper of hopeful idealism. But More and Roger Ascham (1515-68) were under the spell of classical authority, and the latter actually apologizes for using the clumsy English tongue. They wrote for the cultivated classes; but at the same time a popular literature was growing up around the Reformation movement, typified in the racy, idiomatic English of Latimer's sermons. Its simple directness was partly the fruit of his acquaintance with Tyndale and Coverdale's vigorous and happy translation (1525-35) of the Scriptures, a monument of pure Anglo-Saxon speech scarcely tinged with Latinism. The English Prayer Book, which, like the Bible, has done much to mold the speech of later generations, was a compromise in language as in doctrines; one of the most characteristic features of its style is the frequent recurrence of pairs of synonyms—"acknowledge and confess," "dissemble nor cloke"—to appeal alike to the lovers of the sonorous Latin and to the plain, unlettered folk.

The time was at last ripe for England to show the results of long and patient study and assimilation of good models, both classical and Italian. A year before Elizabeth came to the throne, these results were put forth in the publication of *Tottel's Miscellany* (1557), a collection of songs and sonnets, many of them no doubt written much earlier and, according to the fashion of the time, circulated in manuscript until that date. The two chief contributors were Henry Howard, Earl of Surrey, who had closed a brilliant life on the block 10 years before, and Sir Thomas Wyatt, who, like Chaucer, had visited France and Italy on diplomatic missions. Their matter was not so significant as their manner; their great service was the enriching of English poetry by the importation of foreign forms to relieve the monotony into which it had fallen. To Surrey it owes its most powerful and characteristic form, blank verse, and to Wyatt the sonnet, adapted by his happy intuition to the form in which Shakespeare uses it. Yet although they and Sackville showed taste and judgment in the use of their chosen tools, there was as yet little promise of the glorious efflorescence that was to follow. Lyly's refined and elegant artificiality, which has given the language a new word, and Sidney's charming work, which rises at times to a dignity above that of the experiments of a highly cultivated amateur, are not enough to turn the scale.

Yet, before we pass on to consider the drama in this period (for its earlier history, see DRAMA; MYSTERY; MIRACLE PLAY; MORALITY), there is one name which must be set, in the non-dramatic literature of the time, in a position comparable only with Shakespeare's, and one work which more fully than any other in English sums up the manifold effects of the Renaissance. Let Spenser be, as Lamb called him, the poet's poet; grant that he will never take hold of the great popular mass, of whose common life he is so wholly careless; he is yet one of the immortals, and it is to a world beyond space and time that he introduces us in *The Faerie Queene* (1590-96). A Puritan by conviction, though fortunately a Puritan born before his party thought it necessary to war upon everything that was beautiful, he has a moral purpose in his writing, and an allegory lies in wait for us as we wander through his enchanted land. We may elude it, however, and merely note that

the moral seriousness which lies at the root of the poem differentiates Spenser entirely from his Italian model, Ariosto, to whom he owes so much in form. But his style is richer and more elaborate than his master's; he builds up, on the suggestion of the Italian *ottava rima*, the more complex and effective stanza which goes by his name. His childlike delight in the world of sense, which, with all the marvelous resources of his imagery and his music, he strives to make us share, is touched at times by that note of melancholy so common and so significant in the Renaissance writers who stop to think of the shortness and uncertainty of that human life on which they concentrate their highest powers. Among the other poets of the time, Chapman must have a word of commendation, if only for his great translation of Homer, in which, for the *Iliad*, he employed what is probably the most successful metre in English—the swinging “fourteener” of the old ballads.

The causes for the phenomenal, one may say unparalleled, outburst of great literature which distinguishes the age of Elizabeth are many and varied. It was not only that the sunlight of the Renaissance, whose rays had been long in reaching England, now shone in all its radiance there; nor that the invention of printing had made it possible to circulate books by the thousand and raised the gains of authors to a point where they tempted new men into the field; nor that the personality of the Queen, exalted by the hyperboles of poets, formed a focus for their enthusiasm, while her gracious patronage of every art encouraged them to do their best. There was also the life and death struggle with Spain, which called out all that was highest and noblest in the hearts of patriotic Englishmen at the same time that domestic controversies sharpened their wits to do their best for the side they had espoused. There was the rise of the new middle class to increase the number of both authors and readers. And the discoveries of strange, half-fabulous lands beyond the seas seemed a fit pendant to the conquest of whole new provinces of the world; they spurred men's minds on to explore the regions of the knowable and the thinkable.

The drama, whose very nature appealed to that age of stir and vigorous action, was naturally the form that expressed its spirit best, aside from the fact that a century of printing had not yet made reading the daily habit of every man. And since the drama was to be the characteristic literary form of the period, it was most fortunate that it escaped the snares set for it by some of its earliest formal practitioners in England. With the enthusiasm of Renaissance scholars for the work of the ancients, they insisted that the English drama should be modeled strictly upon its Roman predecessor; Seneca was to be the standard of tragedy, and Terence, who had preserved a sort of charmed life all through the Dark Ages, of comedy. The academic school of the time strove hard to enforce this model upon its fellows, aided by Sir Philip Sidney's vigorous blows in his *Defence of Poesie* (1579). The effort was not without its good results in the direction of imposing care for structure and checking too loose imagination; but that it failed was an inestimable advantage to the growth of the literature which is our pride. Marlowe and Shakespeare, the young Davids of the day, tried the armor of Saul before they went out to the

battle, then wisely laid it off. Across the Channel Malherbe and other literary dictators were able to enforce their canons, with the result that French classical tragedy, stately and finished as it is, has never been a living thing, able to thrill and dominate the nation, because it has always been alien from the nation's life.

Sackville and Norton, with their *Gorboduc* (1561), are enshrined in a special place of honor by historians of literary development; the first English tragedy is a noteworthy event. But to Marlowe (1564-93) belongs a much more significant mention. It is he who first showed the way to the construction of a true English drama, first exemplified a unity more potent than the artificial conventions of classicism—that which centres around the development of one mighty character and his deeds. It was he who, though the iambic pentameter was not new to English verse, is yet really the creator of the “mighty line” which became recognized as the regular medium for serious drama and in Milton's skillful hands became even mightier and more perfect. He, like his own Faustus, “sums up for us the Renaissance passion for life, sleepless in its search, and daring in its grasp after the infinite in power, in knowledge, and in pleasure,” and the career which ended so miserably in a tavern brawl, after less than 30 years, was yet full of splendid achievement.

The place of Shakespeare (1564-1616) in a survey of this kind must be in exact disproportion to his absolute greatness. Precisely because of the towering command of that greatness, because “he was not of an age, but for all time,” he has less to do with the general development of thought and expression than many a lesser man. It is not the mighty rock that rears its sturdy shoulders out of the torrent to which we look for indications of the direction and force of the current. In fact, though in a sense the crowning glory of English literature, he belongs not so much to it as to the whole world. He may of course be considered in part as a product of the conditions which affected the general literary growth; but when we stop to consider the other dramatists of his age we shall be struck by the difference more in kind than in degree between him and them; in the bold hyperbole with which Swinburne closes his sonnet, “All stars are angels, but the sun is God.”

The one of his contemporaries who comes nearest to him in rank, Ben Jonson (1573-1637), is also, it so happens, the one whose characteristics are the most instructive for the purposes of a philosophic contrast of tendencies. While the old theory of a personal envy of his master on Jonson's part is now discredited, the fact remains that he represents two points of view diametrically opposite to Shakespeare's. Almost alone in an age of far-going romanticism, he stood unflinchingly for the classical ideals in the drama—for the enforcement of the unities from which Shakespeare had escaped, as well as for wider and happier applications of what we call the classical tradition; for the calm, ordered sanity of that school in an age when the riot of imaginative license ran unchecked. While the struggle seemed fruitless at the time, his attitude was not without its results. The seed slumbered in the ground for a while; but in the end it sprang up and brought forth fruit in the fully developed classicism of Dryden and Pope. The other point of contrast touches the

never-ending controversy between realism and idealism. The former, for our purpose, may be taken to mean the kind of portraiture which is content to seize with fidelity the external characteristics of a man or a woman, while the latter designates the spirit of penetrating insight which goes far below the surface into the eternal verities of human nature—which sees men not only as they appear, but as they are, and perhaps even more as they may be. This was the spirit of Shakespeare, and it is largely because of his possession of this insight that he holds to this day his mastery over the world, while Jonson is read only by students of literature. In his own day Jonson was far more popular than the supreme dramatist; his faculty of hitting off to the life the little foibles and fashions of his generation, of painting (in his own phrase) “every man in his humor,” appealed to an audience who could recognize each detail as part of the daily life of their own circle; but when that generation had passed away, and new manners had come in with another, these old-fashioned humors roused no more than the evanescent interest with which to-day we regard the faded daguerreotypes of our grandfathers. Jonson’s most direct influence upon his age was found in the graceful lyrics which served as models for the cavalier poets, and in his domestication in England of the masque, which made *Comus* possible.

Of the other Elizabethan dramatists not so much need be said. The gradual evolution and sure and steady decline of the drama in England have been treated elsewhere; but a few memorable names, at which the world would have marveled longer had Shakespeare not been, must be chronicled. Dekker’s real if disorderly genius, Heywood’s simple and touching portraiture of domestic life, are worth a word. The “tragedy of blood” which, repellent as it is to modern taste, answered the cry of the time for intensity at any cost, was inaugurated by Kyd’s *Spanish Tragedy*; Marlowe and even Shakespeare touched it in passing; and two really fine poets, Middleton and Webster, signalized themselves in this style, the latter devoting his magnificent power of expression almost exclusively to these horrors. Beaumont and Fletcher can scarcely be named apart, though long and patient study has led modern critics to the conclusion that Beaumont contributed to their partnership the greater depth of thought and constructive power, while his older fellow furnished lyric grace, sentiment, and smooth-flowing diction. Massinger, a Puritan at heart, is at his best when he treats some theme of unworldly idealism. Ford, on the other hand, shows his decadent spirit by his morbid quest of the abnormal in character and situation. Shirley, an imitator in tragedy, is a precursor in the opposite style, writing in the exact manner of the light, graceful trifling of the Restoration comedy.

The greatest prose writer of the early seventeenth century is a man whose services to science, elsewhere dealt with, are even more commanding and universally recognized. Just as Bacon (1561–1626) saw the need of an entire reversal of the old scientific methods before modern science had realized the task before it, so he struck out for himself a way of writing English which anticipated the results of another century of thought on the matter. He had no confidence in the vulgar tongue and refused to intrust to it his scientific speculations; but when

he had occasion to use it, when his *Essays* began to grow under his hand from mere jottings in his notebook into their rounded and satisfying form, he set to work to shape an instrument that should be adequate to his purpose. Saturated as he was with Latin, and going to that language very much for his vocabulary, he saw that it was impossible to write one language by the rules of another, and developed an English kind of sentence, compact, brief, and manageable, in strong contrast to the long, rambling periods of his contemporaries. But prose was not long in developing into something more than a mere convenient instrument. Two writers who were boys at Bacon’s death carried it to a pitch of sublimity and impressiveness which, amid varied modern excellences, has scarcely been surpassed. Uneven, to be sure, sometimes almost too rich, Jeremy Taylor and Sir Thomas Browne at their best will always give delight.

They, far more typical of their age than Bacon, and another man even more typical than they, represent its overshadowing melancholy and its tendency to imaginative contemplation rather than to abstract thinking. Donne (1573–1631) is the best representative in these points, as in the suddenness with which he “passes from moods of earthly passion to moods of religious ecstasy.” As often happens, it was not his strength, but his weakness, that found imitators and created a school; his love of “conceits,” recondite and too subtle analogies and metaphors, which Marini and Gongora were at the same time making the fashion on the Continent, affected a number of the younger poets, of whom George Herbert, Crashaw, and Vaughan “the Silurist” were the most notable; but in him and in them depth and intensity of feeling atone for much that is merely fantastic. Two alternatives to the melancholy which Richard Burton (1577–1640) was at this time anatomizing with so much quaint learning were taken by different men; the cavalier poets, Lovelace, Carew, and Suckling, escaped it by their graceful absorption in the charms of real or imaginary mistresses; while the pastoral writers, Browne and Wither (with whom Herrick and Marvell may be classed, though religion meant at times much to both of them, and the latter went with Milton into politics), delight in the contemplation of nature and the sweet, unspoiled life of the beautiful English country, which touched Shakespeare in his own ways at the beginning and end of his career—in the *Midsummer Night’s Dream* and in the *Tempest*. The same spirit breathes in Izaak Walton, and teaches him to write, little as he may have thought it, an undying classic.

The link between the Elizabethan age and that whose culmination is assigned to the reign of a later queen (Anne) is to be found in the work of Milton (1608–74). In his sonnets (except for the innovation of using the form for something else than love poetry), his elegies, and his masques, he is a true Elizabethan; in his thorough appropriation of the classics, in such technical points as the use of blank verse out of drama, and in many of the articles of his creed, he anticipates that which is to follow. Born eight years before the death of Shakespeare, and the heir of the great traditions of that glorious company, he is in one aspect, as Matthew Arnold called him, “the last of the immortals”; but still more truly he is a product of the new forces that were stirring in the Eng-

land of his youth. The change from the mood of the Renaissance to the sober earnestness of Puritanism may be summed up in Green's vivid words: "The daring which had turned England into a people of adventurers, the sense of inexhaustible resources, the buoyant freshness of youth, the intoxicating sense of beauty and joy which created Sidney and Marlowe and Drake, were passing away before the consciousness of evil and the craving to order man's life aright before God." The magnificent bursts of eloquence which diversify the long reaches of *Paradise Lost*, and the exalted and melody of his shorter poems, "Ovidian," which Tennyson called "a touchstone of poetic taste," set noble models before his successors. Perhaps the greatest single lesson which he taught was the use of the cæsure in the iambic pentameter, which, in its variations according to the demands of a nice ear, makes all the difference between the best of his blank verse and prose chopped up into lengths of ten syllables. He did less for prose than for poetry; in fact, his prose is more rugged and harder to read than that of the earlier Bacon, and he himself confessed that in it he had the use of his left hand only. But what the accomplished scholar failed to do, a simple Bedfordshire tinker, nourished on the Bible and Foxe's *Book of Martyrs*, accomplished with triumphant ease. Bunyan (1628-88) little thought, as he followed the fortunes of Christian on his pilgrimage, that later critics would call his book one of the three great allegories of the world and discover in it at once a revival of the old French romance and an anticipation of the eighteenth-century novel.

The change which took place at the Restoration is often spoken of as if it had been a mere reversion to the temper of mind which prevailed before the destroying flood of Puritanism swept over the land. But this is a superficial view of it. The England of Charles II, whether in politics, in science, or in pure literature, was vastly different from that of Elizabeth. In the first flush of that age of splendid youth there seemed to be no limits to the powers of humanity. Men were not afraid to take, with Bacon, all knowledge to be their province, or to soar with Marlowe into empyrean heights. But the men of the Restoration, like burnt children, dreaded the fire of unrestrained enthusiasm which had kindled so devouring a conflagration. Moderation, the acceptance and study of actual conditions, the establishment of a quiet level of uniform conduct based strictly upon the dictates of common sense, became its ideal. Now for the first time in England criticism went hand in hand with creation. At an epoch when English literature was scarcely known across the Channel, when Bayle was defining Milton as "the famous apologist for the execution of Charles I," who "meddled in poetry, and several of his poems saw the light during his life or after his death," the returning Royalist exiles, on the other hand, brought with them from France the canons of a school of strictness there earlier established. Malherbe had risen to brandish the pedagogue's ferule over the young poets of that country; Corneille and Racine had framed their drama on the strictest classical rules. Dryden (1631-1700) followed them, both in the theoretical discussions of his *Essay on Dramatic Poesie* and in his practice: the classical school restored the unities, kept tragedy and comedy strictly separate, and usually employed rhymed couplets in

preference to blank verse. The tragedy of the Restoration, in which, besides Dryden himself, Otway must be mentioned for at least two imperishable plays, was largely a survival or an imitation. Comedy, however, has an importance of its own, if only for its exact reproduction of the tone and manners of the society of the time. It follows, not the romantic treatment of Shakespeare, but the realistic fidelity of Jonson and Shirley in the early or more consciously that which taught its authors in France. Etherege and Wycherley, Congreve and Vanbrugh, are corrupt and cynical because such was the society in which they lived and for which they wrote. But we shall scarcely need to touch the drama again; from various causes it has practically ceased to have a living connection with literature, despite the brave attempts of no less poets than Tennyson and Browning and Swinburne to revive its ancient glories; there are clever comedians to-day, yet when we look for a comedy which will live in libraries, we must go back to *The School for Scandal*, *The Rival*, and *She Stoops to Conquer*—to the last quarter of the eighteenth century.

The tendency of the Restoration world to a strictly regulated uniformity, alluded to above, found expression in nondramatic poetry not only by an increasing preference, in subject, for the life of an organized and cultivated society, the life of the town, but by the almost universal adoption of a single form—the heroic couplet—which was to dominate English verse for more than a century. The form was not new; it had been used long before by Chaucer, as it was to be used again by Keats, but with a radical difference. In the hands, first of Edmund Waller (1606-87), then of Dryden and his eighteenth-century followers, each pair of lines as a rule contained one complete thought, limited and condensed by these narrow bounds. The influence of Dryden on prose was not dissimilar to that which he exercised on poetry. It was not, perhaps, so consciously exerted; prose had not even yet attained the dignity of a form worthy the careful attention of the artist. What he strove to do was to make it a fit vehicle for the conveyance of well-defined thought; and to this end he abandoned the long, rolling periods of the Elizabethan and Caroline prose writers—as in poetry, he "reduced the unit of treatment to manageable size"—and determined the structure of the modern sentence as it has ever since been preserved. Thus, in his own production in both kinds, as in his singularly influential and epoch-making criticism, Dryden bodied forth the spirit of his age and molded that which was to follow.

The eighteenth century was characteristically a period of unrest. Its intellectual ferment was fostered by skepticism, which invaded every domain. The concrete was engulfed by a flood of abstract speculations, and in industrial spheres the result was wholesome. Rationalism and deism were accompanied by an analytic study of man, almost exclusively, however, on his intellectual side. The spirit of man had suffered eclipse. All this we find in the poetry of the period. Pope (1688-1744), as the spokesman of the school, had declared the proper study of mankind to be man, and man was accordingly dissected. As a social unit, whenever so regarded, man is treated most flippantly, and the affections are mostly ignored. Indeed, it was a tenet of the philosophy then current that man was a most despicable thing, and yet it arrogated to

itself peculiar wisdom. Pope's adoption of this attitude was the sheerest affectation. From poetry in general the note of sincerity was missing, and the great god Pan was dead. In the evolution of literary ideals, however, ideals which find completest acceptance to-day, the eighteenth century is of the first importance and can boast some of the most delightful masters in both prose and verse. What these new ideals are may be indicated by a brief survey of these writers.

In philosophy, theology, history, and oratory the century takes high rank. Berkeley (1685-1753) attacked the sensation theory of Locke (1632-1704) and insisted on what has been termed a theological idealism. Hume brought admirable common sense and a strenuous skeptical spirit to bear on the theory and in his turn assailed Berkeley's thesis. Of other philosophical writers one may mention Hartley, Paley, Reid, Shaftesbury (of the *Characteristics*), and Dugald Stewart; and, though less important, Bolingbroke was more faithfully representative. Deism was the common target of the clergy. When Anthony Collins published his *Discourse on Freethinking* (1713), Bentley, Warburton, and Berkeley appeared in rebuttal. But the classic of this field is the *Analogy* (1736), in which Butler had the good sense to bear in mind that his work was not an absolute argument. The contrasts of the century cannot elsewhere be more manifest than in the rise of the Methodists. Where theory was impotent, practice availed. The pious life and strong personality of Wesley (1703-91) and the fervid preaching of Whitefield (1714-70) furnished the necessary corrective to the atheistic and deistic conception so widely prevailing. This countermovement was supported by a fine poetry of devotion, the work of the no less beautiful spirit, Charles Wesley, and by a multitude of hymns, many of them devotional rather than poetic, from the pious Watts.

To history Hume (1711-76) brought style and philosophy, but inadequate research, and his work has consequently suffered from the charge of inaccuracy. But though it is marred by a partisan spirit and is almost a Tory evangel, the historical sense is true, the method luminous, and the recognition of the life of the people as more important than statistics of dynasties introduces a new conception of historical composition which Macaulay and Green were not slow to appreciate. Smollett supplemented his fellow countryman's work, and Robertson wrote of Charles V and of America. It is Gibbon, however, who is the commanding figure in history. His stupendous plan was supported by equal resolution and fidelity. Learned, philosophic, stately, the *Decline and Fall of the Roman Empire* (1776-88) is a work which in its somewhat grandiose but still authoritative periods has not a little of the dignity of the epic. But perhaps the book of the greatest practical value, a legitimate response to the wide industrial awakening, is Adam Smith's *Wealth of Nations* (1776), the beginning of the science of political economy. In oratory the century was even more commanding. and Chatham, Fox, Pitt, Sheridan, and Burke are names which in this sphere are paramount, though Horace Walpole preferred Chesterfield, and Bolingbroke gained considerable prominence. Of Burke, indeed, it is difficult to determine whether he was greater as a writer or as an orator. He began as a man of letters, and such, despite

his political activity, he essentially remained. Though it is commonly believed that his speeches must have been better read than heard, Macaulay in his most energetic manner pictures the effect of his oratory in the Hastings trial as overpowering. Unhappily for his reputation as an amiable man, his vehemence of invective (as against the Duke of Bedford) was second only, if indeed second, to that of "Junius." The companion of the most cultured men and women of his time, he was perhaps the greatest of them all, and never more himself than when he befriended the starving poet Crabbe.

In the eighteenth century we find the beginning of the periodical essay, which enjoyed high favor as a literary form and became the vehicle of some of the best writing in the whole range of English prose. (See ESSAY.) In 1709 Steele established the *Tatler*, in which he began the publication of short articles on literary and social topics. Soon he had the hearty coöperation of his old schoolfellow, Addison, who was peculiarly fitted for such work. Together they founded the *Spectator* (1711), in which appeared the chivalrous Sir Roger de Coverley, who may dispute Robinson Crusoe's title to the position of the first notable character in English prose fiction. Steele's essays were marked by ease and naturalness and somewhat atoned for the vicious taste of the sentimental drama to which he unworthily lent his name. Addison brought to prose a grace and an ease which it had scarcely known except in Shakespeare; and when his *Campaign* and his *Cato* are forgotten, the elegant simplicity of his essays will still charm new generations. A wonderful contrast, in both person and manner, is that between these genial humorists and the moody dean of St. Patrick's. Swift must always be remembered as a man of great force of mind and character, set awry by disappointment and bodily suffering. Conscious of high endowments, he was inspired by his sense of injustice and neglect to write *Gulliver's Travels* (1726), the classic of injured merit and of angry revolt against the shallow discriminations of society and government. His morbid spirit became terrible in the intensity of its hate for mankind. With Swift the style was the man—fearless, aggressive, sturdy. Yet he made warm friends and inspired a singular devotion in two women; beneath that rugged exterior there must have been a naturally tender heart, which would have leaped to meet a brotherly recognition.

For homely simplicity and directness, the nervous style of Defoe at his best has rarely been excelled. His numerous pamphlets and his verse are practically unknown to the general reader; but *Robinson Crusoe* (1719), the classic of the race of boys, is a masterpiece of adventure. His other stories, little read, differ from the modern novel in the absence of a plot, but resemble a special phase of it in being written with a purpose—in his case to enforce the morality of the middle class, to which he belonged and for which he wrote. Sterne's chief work, *Tristram Shandy*, is as far as Defoe's tales from possessing the coherence and the regulated progress of events which mark the modern novel; it is capricious and uneven, while, unlike Defoe, Sterne deliberately rebels against the moral standards which Addison, e.g., had enforced on his generation. But his humor, which has caused him to be classed now with Rabelais, now with Cervantes, his finished senti-

mentalism, as distinguished from genuine sentiment, and his power of creating characters endowed with an absolute reality—all these unite to give him a conspicuous and very special place.

The novel proper began with Richardson, though it is probable that he was unconscious of creating a new literary *genre*, which was destined to overshadow all others in multiplicity and popularity. His method seems to have meant to him a sort of expansion of the drama; he calls *Clarissa Harlowe* (1747-48) "a dramatic narrative." There is in him much of the tedious prolixity of the French romances; but he possessed the faculty of interesting the reader, partly by a quality which has lost its appeal for us, but to which Lady Mary Wortley Montagu, e.g., bears abundant witness—his realistic fidelity to the types of character and the manners of his own time. But even had Richardson no merits of his own, we should still be grateful to him for provoking Fielding to enter upon the writing of fiction. Fielding's variety of experience, his apprenticeship in the drama and in periodical literature, his accurate observation, united with his native capacity in all kinds of literary endeavor, admirably fitted him for the . . . scope of the novel. Great in plot, . . . power to marshal all details and to conduct them masterfully to the dénouement. He is another of the great humorists, and he is still modern. Before *Tom Jones* (1749) appeared, a new writer of fiction had published *Roderick Random* (1748). Smollett had much the same reason for cynicism as Swift, he fancied, and the accent of his work is pessimistic. He is said to have had greater influence on the development of fiction than any other writer of his time. His work, however, smacks of the far-away period of Cervantes and Le Sage and does not enthrall like that of Fielding. Goldsmith's charming idyllic story of *The Vicar of Wakefield* appeared in 1766 and, winning Goethe at once, has since won the world by its "happy reinforcement of the theme of domestic bliss and tranquillity." Sharply contrasted with its grateful simplicity is Johnson's *Rasselas* (1759), the style of which is characteristically ponderous. It is interesting at least as the sole attempt of the great autocrat in a form for which his aptitude was anything but conspicuous. Here also belong Miss Burney's *Evelina* and *Cecilia* (1778 and 1782), both of which are said to have been as eagerly received as Scott's work was subsequently to be. Assuredly it would be a tribute to any author to have Johnson, Burke, and Reynolds become so far absorbed that they were unwilling to put the book down, the two latter spending the whole night on it. Here, too, should be mentioned Godwin, for his *Caleb Williams*, as well as for his abstract philosophic work; Horace Walpole, for his *Castle of Otranto* (1764), no less than for his *Anecdotes of Painting, Memoirs*, and supremely fascinating letters; Lewis, for his *Monk* (1795); Mrs. Inchbald, for her *Simple Story* (1791); and Mrs. Radcliffe, for her *Mysteries of Udolpho* (1794). The first of all this company in sheer power is easily Henry Fielding, while for grace as inimitable as it is distinctive Goldsmith leads; Miss Burney excelled in the depiction of domestic character; with Walpole began the novel of mystery; from Lewis and Mrs. Radcliffe we receive those "tales of terror" which were afterward wrought out

and with Godwin the "novel with a purpose" enters upon its long career. It should be noted that here woman first appears conspicuously in English literature; and not alone in fiction, as becomes evident when we consider Lady Mary Wortley Montagu (1689-1762) and Mary Wollstonecraft (1759-97).

Great as was the eighteenth century in prose, its claims upon us are yet greater in the field of poetry. The two dominant figures of the period were, indeed, Pope and Johnson; but their rigid and sometimes absurd classicism was in their own day beginning to be superseded by the romantic revival, whose culmination constitutes the brightest chapter in our literary history after the Elizabethans. For their contemporaries they were the overshadowing poets. In Dr. Johnson (1709-84) we find a man who by virtue of his vigorous personality, even more than Dryden and Pope, stood out from his age. What he lacked in intrinsic literary preëminence he supplied by a tyrannous dictatorship. His impetuous prefatory "Sir!" was sufficient to intimidate, if not to convince, and his reign as literary lawgiver ended only with his life. For all his versatility, he is now largely a literary memory and survives rather as a personality. His *Lives of the Poets* discovers gleams of genuine critical insight, but, on account of ingrained prejudice, his judgments are untrustworthy. His "Vanity of Human Wishes" and his "London" are good imitations of the Popian satire, but they must suffer by comparison. The play *Irene* is known to few. The *Rambler* and the *Idler* are heavy successors of the periodical essay made so popular by Steele and Addison. But the preface to his *Shakespeare* is deservedly famous for its uncommon good sense, and the *Dictionary* is a monument of lazy industry, not without absurd eccentricities. The man, however, who could inspire perhaps the best biography ever written, merits, aside from literary considerations, all the immortality he enjoys. Pope it is, however, who inevitably assumes the largest claim on our attention when this century is thought of. He is the representative voice, his the characteristic manner. By some denied the title of poet at all, he was by a few classed with Shakespeare as a twin glory; and, for obvious reasons, he is, after the great dramatist, the most quotable of English poets. To apothegmatic thought he joined admirable conciseness of phrase. We must not confound his own viewpoint with that of a later day. If we take exception to his poetical ideals, we must allow that in his own time he was consummate and unapproachable in their execution. It is, however, the consensus of opinion that he was a clever versifier and epigrammatist rather than a poet in anything like the highest sense of the term. His mental alertness is always seconded by mechanical skill. But, though more perfect in polish, his couplets are far from equal in beauty and variety to Chaucer's and Goldsmith's, and much below Dryden's and Browning's in strength. Like them, he could not snatch a grace beyond the reach of art. He polished until he polished all spontaneity out of his verse. It affects us as machine-made—the work of an artisan rather than of an artist. No wonder the fine poetic soul of Keats recoiled from it as resembling the rocking of a hobby-horse. From these considerations one is prepared to admit that Pope

not equivalent to damning with faint praise. It is equally true that he is peerless in the mock-heroic. Unquestionably *The Rape of the Lock* is a masterpiece of its kind, but it is too characteristic to warrant the praise sometimes bestowed. He was by temperament finely constituted for satire, and though some of his friendships were warm, *The Dunciad* reveals him alike at his best and at his worst. The "Essay on Criticism," the "Essay on Man," and the various "epistles" discover the clever man of letters with a remarkable facility for rhyming the literary canons and philosophy current in his day. For any intellectual force which the ideas themselves may possess he can present no legitimate claim—he is simply the adapter, though his alone is the form. He was for the most part as devoid of emotion as of imagination but there is one poem in which a real human interest predominates. The least distinctive, it will appear to many his best. "Eloisa to Abelard" is a soliloquy, which, while inevitably artificial, yet appeals to the heart and brings the tragic lives of the ill-fated pair with a degree of vividness before us. Perhaps more than anything else this poem, so little heard of, reveals to us the potential maker. If Byron's somewhat extravagant admiration should be shared by others, or if the present common acceptance should hold, it would seem that it must be by virtue of historical criticism and the personal estimate rather than because of any absolute poetic preëminence. But let the critics do and say what they will, the little man whose indomitable will sustained the life which was one long disease, and who under difficulties that would have appalled a weaker spirit wrought stoutly on, will never cease to have a following.

The crowning glory of the century, however, was its least characteristic poetry. Now returns that fresh breath of field and woodland, absent since Milton, but never lacking since; and this time the love of nature for its own sake. It is conspicuous in Gray, Thomson, Cowper, Goldsmith, Collins, and Burns; culminates in Wordsworth; and pervades, and may well-nigh be called the touchstone of, the most of nineteenth-century verse. Gray (1716-71) had the scholarship befitting his fastidious classical taste, and yet his "Elegy" breathes the very spirit of the time in its genial appreciation of common brotherhood and its catholic appreciation of virtue wherever found. It was a new voice, and sweet are its accents still. By this utterance the man is best known, though his other poetical work is memorable, and the *Letters* are almost incomparable. The romantic spirit was in the air and became rapidly infectious, but the traditions of a staid classicism obstinately persisted and incongruously mingled with the more unrestrained newcomer, notably in Thomson.

It is this new ideal—romanticism—which, after the novel, gives the eighteenth century its strongest claim to distinction, so far as tendencies are concerned, and the tracing of the movement from its beginnings is no less instructive than alluring. Cardinal dates must always mark the tremendous significance of Percy's *Reliques* (1765). Of perhaps less importance, but similar in aim and spirit, Ossian (1760-63) exerted great influence on the time, now fairly alive with new things. Whatever the merits of the controversy about its value or

authorship, we are surely indebted to Macpherson for a work quite unique. The marvelous boy Chatterton is one of the many evidences of the prodigality of this renaissance. Like poor Swift, dying atop, the melancholy Cowper and the sensitive Collins had yet to sing—the one in meditative strains, the other in madly impetuous lyrics. Thomson's *Seasons* had great popularity in Pope's own day and was commended by the man who fancied he could invent nature, so completely had it been forgotten. The "Pastorals" is the dismal result. But Thomson's highest achievement is the "Castle of Indolence" (1748), which might well be mistaken for the witchery of Spenser himself. For Goldsmith the world cherishes unmixed affection. He is dear as poet, critic, dramatist, novelist; and if his history and science will not bear closest scrutiny, the charm of the style is amply sufficient to redeem errors in matters of fact. And for all he was, in a worldly sense, impractical, he brought so rich a fund of common sense to poetry and the drama that he demolished the sentimental stage and invested descriptive poetry with a charm as grateful as it is rare.

For historical if not for better reasons, Beattie should be mentioned for his *Minstrel*, Shenstone for his *Schoolmistress*, Akenside for his *Pleasures of the Imagination*, Young for his *Night Thoughts*, Churchill for his *Rosciad* and other satirical work, Blair for his *Grave*, Dyer for his *Grongar Hill*, Gay for his *Beggar's Opera*, Ramsay for his *Gentle Shepherd*, and Parnell for his *Hermit*. The mystical Blake (1757-1827) had a nature sublimely artistic, and his *Songs of Innocence* and *Songs of Experience* are alike valued for imaginative poetry and for symbolistic art. In no indefinite sense he is akin to Dante Gabriel Rossetti. Crabbe (1754-1832) is noteworthy for his merciless fidelity in depicting real life in his *Village* and his *Tales of the County*, and Bowles for his sonnets, which Coleridge greatly admired. But, alien as he is from its spirit, the most consummate flower of the century, the most spontaneous genius of its poetry, is Robert Burns (1759-96). If ever poet was inspired by something beyond himself to sing his inner raptures, it was this Scottish peasant. Head, heart, and eye alert, he sang to a rapt world such strains as are seldom heard. For fervor, genuine manhood, absolute sincerity, emotional power, and essential poetic beauty he has few peers. Education would have spoiled him; he loses his sureness of touch when he essays the classical English, but he goes straight to the heart with the winsome grace of his Doric Scotch. That he should have arisen in an age which had been given over to artifice under the delusion that it was art is not amazing, for he was a lyric poet born. He was democratic in a time when to be so was to be solitary, radically true when cant and hypocrisy were rampant, and his satire is the better because his heart was naturally so gentle and loving. He had a sense of worth, a sanity of thought, a largeness of vision which made him resolute and unfearing alike in championing the true and in lashing the false.

It is not to undervalue the work of such men as Burns and Gray that one singles out the names of Wordsworth and Coleridge as those of the poets who really determined once for all the character of nineteenth-century poetry,

gave it back its freedom, and widened its field of vision. The year 1798, which witnessed the publication of the little anonymous volume of *Lyrical Ballads*, which included poems of both Wordsworth and Coleridge, is, then, the epoch-making date from which these great changes are to be reckoned. The change was vast, both in matter and in manner. In style the young and unknown authors boldly contended for the right to use the language of everyday life in place of the conventional words from which a century of passing from hand to hand had obliterated every characteristic feature. In subject they struck boldly away from the manners of the town, or of townsmen, and as Arcadian shepherds, which had been the staple of the eighteenth-century poets. When Pope wrote

"The proper study of mankind is man,"

he meant man as displayed in the elegant circles of London or as conceived in the speculations of deistic philosophers. Wordsworth studied man in a vastly broader sense and found the cottager or the wagoner as much a man at least as the beau. Like most far-reaching reforms, this went at times too far; simplicity, which, rightly understood, is a canon of the greatest art, became childish in his hands at times and lent a handle to the mocking parody of the Smith brothers in their clever *Rejected Addresses*. But he had struck the right note—a note which is so familiar to us from the whole drift of nineteenth-century thought that we scarcely discern how valiant a departure from the mode it was.

Coleridge, whether or not he was conscious of it himself, stands out clearly to us a century later as the necessary complement of his associate. While Wordsworth showed the beauty, the depth, that could be found in the most commonplace of lives, Coleridge rather brought home to a nation that had forgotten the daring flights of the Elizabethan age the reality of the invisible world and paved the way for the Pre-Raphaelite movement of half a century later. His influence on his century, however, was exercised less through the medium of his poetry than of his prose, through his own pregnant thought on deep questions of philosophy, of religion, and of politics, and by the current of German tendencies which he set flowing amid the still waters of English life, powerfully seconded by Carlyle.

If Wordsworth influenced the thought of his successors in poetry for the whole century that has followed, their form was more powerfully affected by the man who died with so many dreams unfulfilled that he spoke mournfully of himself as "one whose name was writ in water"—John Keats (1795–1821). Standing utterly aloof from the fierce controversies of his time, caring less than nothing for the questions of emancipation which were so vital to his friends, absorbed in the practice of his art, Keats showed later poets how to seek out "the right word," the word which should express poignantly their inmost thought, no longer content with epithets which had been handed down by a long line of polite predecessors; in Lowell's happy phrase, he "rediscovered the word." He wonders that lay enchanted in

exacerbated by what he felt to be the injustice of society to himself, found voice in passionate protest against existing institutions, against anything that could cramp or fetter the individual in his search for the satisfaction of his desires. The thing became epidemic; the figure of the reckless young lord, magnified to heroic proportions, Ajax defying the lightning, was the ideal of hundreds of other high-spirited young men, not only in England, but on the Continent; and the rolling Byronic collar became the badge of a generous independence of thought. The fact that Byron voiced the spirit of his generation with so much real force and fire is at once an explanation of his immense and immediate popularity. He will always be the poet of hot-headed youth; but it is possible to see now that he was carried by the rush of the moment into a place far higher than he can hope permanently to hold. Those who doubt this may be sent to the criterion proposed by a living judge of rare equipment; it is simply necessary to read Byron immediately after a course of one of the poets whose place in the first rank is indisputable—after Shakespeare, after Spenser, after Shelley—in order to rise from the reading with the conviction that, undeniably great as were his gifts, he is not of their company.

The name of Shelley (1792–1822), just mentioned, and always to be mentioned with reverence for the loftiness of his flight into the empyrean, for the splendid attainment of his music, for the moving appeal of his lyrical cry, yet must have less space than that of Keats, e.g., in a survey like this of tendencies and growths rather than of men, since his genius was less seminal, less formative. With a purer, less selfish enthusiasm than Byron's for the rights of humanity, he too sang the paean of that universal freedom which seemed to be dawning on the world, and died before he could be convinced, with Wordsworth and Southey, that he had mistaken the glare of a sunrise for the sunrise. An outcome of the excitement of this period was the revival of a spirit of patriotism and nationality, akin to that which had been so potent in the Elizabethan days, but which the calm, cosmopolitan culture of the eighteenth century had rather lulled to sleep. It is represented by the stirring war-songs of Thomas Campbell (1777–1844), a convert from classicism to romanticism; by the poetry as well as by the novels of Scott (1771–1832); and by the Irish lyrics of Thomas Moore, far more genuine and worthy of preservation than the artificial decorativeness of his Oriental tales.

But the most significant change which took place at the outset of the nineteenth century was the linking of that age to the forgotten inheritance of England's past. The eighteenth century had been practical, self-centred, self-sufficient; if it sought an example at all outside of itself, its eyes were turned toward Greece and Rome. The Middle Ages were to it a period of barbarism, unworthy the attention of serious men. Thus Addison went to Rimini, and, though he knew that the Malatesta had been lords there of old, while he notes a Roman inscription "still legible, though wrongly transcribed by Gruter," and discusses the learned Frabetti's ingenious conjecture on Trajan's pillar, had not a word to say of the story of Francesca, which to modern minds is the chief in-

The revolt from the conventionalities of the preceding age showed itself in another and a more startling way. The spirit of Byron (1788–1824), naturally restless and impetuous, and

terest of the place. The reversion to a realizing sense of continuity in English history and letters is the work mainly of two men—Scott in life and Charles Lamb (1775–1834) in literature. The work of the former becomes of great significance under this aspect; it was he who, by his rendering mediæval life and “the spacious times of great Elizabeth” vivid and actual, made it possible for Carlyle and Ruskin to analyze modern life by the method of contrast; it is not too much to say that he paved the way for that important and far-reaching movement by which the Oxford Tractarians changed the religious attitude of England and turned men’s faces toward Catholic antiquity. His other great achievement was his triumphant mastery of a kind of literature which had been unsuccessfully attempted for two thousand years—the historical novel. Lamb’s work was the revival of the older English literature, neglected since the Restoration. The attitude which made it possible for Pepys to call the *Midsummer Night’s Dream* “the most insipid, ridiculous play that ever I saw in my life,” which allowed Dryden to win applause by a frigid recasting of *The Tempest*, and which culminated in the honest declaration of George III that he found most of Shakespeare “very poor stuff,” was reversed by Lamb’s discerning enthusiasm for the glories of Elizabethan literature, which came upon his generation with all the freshness of a new discovery. In this work he was ably assisted by Hazlitt and Leigh Hunt, of whom the former had a critical faculty even surer and wider, if not more delicate, than Lamb’s own. The influence of these men on the prose style of their successors, in the direction of flexibility and grace, was exceedingly valuable. Stevenson especially, of later essayists, owes a great debt to one of them, which he frankly acknowledged with his “though we are mighty fine fellows nowadays, we cannot write like Hazlitt.”

Another kind of prose, excellent in its way, was written about the same time by De Quincey (1785–1859) and Landor (1775–1864). It had less consequence, though Ruskin exemplified it in a style which, at its best, lacked only the care forbidden by the multiplicity of his other interests to set it in the very highest place. This was the ornate and highly colored prose which in the earlier English we associate with Jeremy Taylor and Sir Thomas Browne—full of “purple patches” and sonorous Latinisms, and with a majesty and a melody that make the organ its nearest type in music. Living all through the heyday of the romantic triumph, Landor remained (in his poetry, at times of rare excellence, even more obviously than in his prose) calmly classical, “striving with none, for none was worth his strife,” handing down a tradition which was worthily continued by Matthew Arnold, and honored in his old age by a singer in many ways so far from the classical temper as Swinburne.

The great reviews and magazines which came into existence early in the nineteenth century had an important effect upon its literary progress. The *Edinburgh Review* was founded in 1802 to uphold the principles of the Whig party, by Sydney Smith, Brougham, and Jeffrey, and the last named soon became its editor. Its unsparing personal criticisms of contemporary authors caused an immense sensation and evoked Byron’s scathing retort entitled *English Bards*

and *Scotch Reviewers*. The *Quarterly Review* was established in 1809 as the Tory organ; the truculent Gifford was its first editor, and Southey, Scott, and Lamb among its contributors. Somewhat later came *Blackwood’s Magazine*, for which Wilson wrote his *Noctes Ambrosianæ* and Lockhart his trenchant criticisms. There was also the *London Magazine*, to which Lamb contributed his *Essays of Elia* and De Quincey his *Confessions of an English Opium-Eater*, and for which Carlyle, Hazlitt, and Leigh Hunt also wrote. All these great periodicals exerted a powerful influence upon literature, especially in the development of the art of criticism, which has become almost an independent branch of letters.

The first force of the philanthropic outburst, the realization of the brotherhood of man, which Wordsworth and Shelley in their different ways had expressed, had partly spent itself, as Europe settled down after the revolutionary period of *Sturm und Drang* to a reaction in favor of orderly and settled life, comparable to that which was noted above as following the violent struggles of the Reformation and the rebellion. One author of the second quarter of the century typifies better than any other the mood of placid self-satisfaction with things as they were—Macaulay (1800–59). His spirit of cheerful optimism, his calm assurance that the existing British constitution was the most wonderful product of the human intellect, and everything for the best in an admirably ordered world, represents fully the characteristic temper of the England of his younger days. Out of this complacency the nation had to be roused by a rude shock. The voice as of one crying in the wilderness, the trumpet tones which startled this complacent England, were those of Thomas Carlyle (1795–1881). It is difficult to realize how electrical was the shock of his sudden onslaught, how the impetuous torrent of this rough eloquence carried away all the thoughtful younger men of the day. As Byron a generation earlier had made a picturesque melancholy the fashion, so Carlyle set his contemporaries to studying social questions, insisting that they should realize the crying need for many and sweeping reforms in the state of society which they had fancied so perfect. With the acceptance of his gospel begins a new epoch in English letters. They were for the first time closely and intimately connected with the life and the progress of the whole race. Addison had indeed written with a moral purpose, thinking to soften and refine the manners of London society; but Carlyle went much further than this and set in motion springs which have never ceased to act. If we wish to bring home to ourselves how far we have traveled under this powerful impulse, we have only to try to imagine Sir Walter Scott reading, one need not go so far as to say the novels of Mrs. Humphry Ward, but even those of George Eliot. The criticisms of Carlyle’s style, which caught the ear for the moment and have tempted many a young writer into unhappy efforts at imitation, have passed away; but his spirit lived after him in the earnest crusade against immemorial abuses which enlisted the best energies of widely differing minds. England was at last awake. On every side were the stirrings of new life—in politics with the Reform Bill and the Anti-Corn-Law League, and the teachings of the Owenites, for the first time called Socialism: among religious teachers with the Broad Church movement of Maurice (1805–

72) and Kingsley (1819-75), and the Oxford Tractarian school, both of them full of social suggestion; with the bold searching into the depths of the human heart by Tennyson and Browning. Thackeray cried out against shams in the very spirit of *Sartor Resartus*, and Ruskin's fiery heart could never rest while there was a wrong to redress, a man or a woman to raise to a higher plane of thinking and living.

The names of Tennyson (1809-92) and Browning (1812-89), though both these poets lived until the agitations of the thirties seemed ancient history, are connected with the middle of the century, as well as by their work with this period, their first books having appeared at the opening of this stirring decade. Both continued for over half a century, in widely differing ways, to express or to stimulate and inspire the thought of thousands of readers—of more thousands than the words of any English poet had ever reached before. Tennyson's audience was by far the larger, if perhaps less fit; he made less appeal to intellectual alertness, and the average reader, who turned away puzzled from most of Browning, felt at home in the easy and at times commonplace sentiment of the Laureate. The work of *In Memoriam* was perhaps the most valuable that its author did for the thought of his age; it was the courageous facing of the new discoveries and theories in science, which seemed likely to make an end of belief in a spiritual world, and the showing that this world, and poetry which knows its ways so well, were not to perish before the Darwinian hypothesis. But in form, in technical achievement, in the flawless finish of his style through all the kinds of poetry which he attempted, he has had few equals. There is scarcely one of his great predecessors whose peculiar excellence he has not caught, fusing them all into a style unmistakably his own. Browning had far less perfection of finish, but much more robustness of nature and of thought. Tennyson believes in and preaches constantly an overruling law which shall ultimately bring order out of chaos; his brother, not rival, poet (there was no room for jealous emulation in either of their souls), since his chief interest was in the life of strong single souls, found satisfaction for his undaunted optimism in the fact that it was possible for such souls to make their life by courage and truth. His works have been well called "a permanent storehouse of energy for the race, a storehouse to which for a long time to come it will in certain moods always return." His wife, Elizabeth Barrett Browning, though she was long far more popular than he, is chiefly interesting from the noble and ardent way in which she throws her whole soul into the cause of the oppressed, in England or in Italy. Once at least, in her wonderful *Sonnets from the Portuguese*, she rose by her passionate love for her husband to really great heights of poetry. A greater poet, however, probably the most notable among the women singers of the century was Christina Rossetti, the sister of the Pre-Raphaelite leader.

A link between the prose fiction of the eighteenth and that of the nineteenth century is not found in Miss Austen (1775-1817), sure in dramatic instinct, unimpeachable in the construction of her plots, and unerring in her observation of the external accompaniments of character as she is; she is a realist, presenting "humors" (in Ben Jonson's sense) and going little below the surface. The connecting link is rather a woman

less known and less considered, Maria Edgeworth (1767-1849), who suggested the right use of local color to Scott—and, be it said by the way, to the great Russian, Turgenev, his studies of peasant life—and who saw that an effort at accurate portrayal of the seen need not hinder a vivifying perception of the unseen. After Scott the novel greatly widened its scope, to deal, as did the drama under Elizabeth, with all the problems which human life has to face. Three writers who made their fame in this department express the temper and depict the people of the middle of the century—Thackeray (1811-63), Dickens (1812-70), and George Eliot (1819-80). Their absorption in the social problems which we have seen coming to the front made them realists, and with succeeding generations they have suffered from this attitude. Dickens especially, whom 20 or 30 years ago it was heresy to decry, is now far less read, for the reason given above in the treatment of the Elizabethan realists: his questions are no longer actual—we are not moved by the delays of Chancery or by ancient abuses in prison discipline—and his people, living as they were to his contemporaries, are to us no more actual than the quaint figures of old sporting prints. Thackeray's problems have more of the permanent about them, and while his leisurely, discursive manner has become old-fashioned, and his inability to construct a consistent plot is apparent, he must always hold a very high place in English fiction. George Eliot is not only remarkable for having, as a woman, been among the first to take her place by the side of the men in strenuous discussion of public questions; more than either of the novelists just named, she saw life steadily and saw it whole; and far more than they, she reflects the questioning, uneasy temper of her generation in regard to the great problems of the soul. Not alone in her novels, but in the poetry of Arnold (1822-88) and Clough (1819-61) does this same spirit find expression.

Arnold, like Aaron of old, stands between the dead and the living—between the old faiths, the old attitude towards life, so largely outworn and discarded, and the new temper of hopefulness in the development of the race and its ability to face new problems; but, unlike Aaron, he holds no smoking censer of propitiation to slay the plague which he feels to be devouring his generation. In thought he is thus eminently characteristic of his time—the period of transition which covers the middle of the century. From the fact that his poetry is tinged throughout with half-despairing melancholy, it is rarely appreciated at its full value until the illusions of youth have passed away; like his master, Wordsworth, he is the poet of middle age. But in his prose, even more classical in its quality than his verse, he has appealed to a wider class and done a more enduring work. He is the supreme critic of the early Victorian period, not only in the literature, but in life as well. He turned from the deep problems in which he saw no hope, and devoted himself to preaching the lower but still valuable gospel of culture. Carlyle and he represent perfectly Heine's antithesis between the Hebraic and the Hellenic elements in human nature—the one holding up an ideal of stern, uncompromising devotion to duty, and promising no reward but the approval of the conscience; the other inculcating the broad, free, mobile open-mindedness of the Greeks—the apostle, in the phrase which he borrowed from

Swift and made his own, of "sweetness and light."

Opposed to Arnold's urbanity, to the temper which has caused him to be called "a spiritual man of the world," stands in sharp contrast the attitude of two great contemporary authors, Ruskin (1819-1900) and Newman (1801-90). For our purpose the dictatorship so long held in matters of art by the one, as well as the notable and epoch-making ecclesiastical career of the other, must be neglected; but we are bound to take account of their general influence upon the thought and the writing of their day. They were alike in more than one external feature of their magnificent prose; no nineteenth-century styles, e.g., show more abundantly and more happily the effect of a lifelong saturation in the majestic and beneficent English of the Authorized Version of the Bible. But they have a deeper kinship in their equal insistence upon the reality of the unseen, the spiritual world. Whether he wrote of art or of political economy, this lay at the very root of Ruskin's firmest beliefs; and thus he was naturally forced to look backward rather than forward—away from the future with its increasing zeal for material progress, to the past of the Middle Ages with its universal and vivid sense of the reality of the invisible and the eternal. Newman's abhorrence of the intellectual anarchy of his day drove him in the same direction and brought him, after much tossing on troubled seas, "to the haven where he would be." Both of them are thus once more opposed to Arnold; while the temper of his mind was purely classical, they came in different ways to share the spirit of the romantic movement in its revulsion from a prosaic and sordid present.

The same attitude of mind was even more definitely exemplified at the same time by the rise of a school which powerfully affected both art and poetry, though it is only with the latter that we are here concerned. The Pre-Raphaelite Brotherhood had not, at least in poetry, discovered any new truths; their cry for a return to nature, their appeal to "the spirit of wonder and mystery in human life," had both been articulated a half century earlier by Wordsworth and Coleridge; but to a new generation their teaching came with a new value. The preëminence of Rossetti (1828-82) has overshadowed a number of lesser men who yet deserve much more than oblivion—John Lucas Tupper, e.g., an admirable poet now scarcely known, of one of whose lyrics Rossetti himself said that had it been the writing of Edgar Poe it would have enjoyed a worldwide celebrity. But the chief of the school, in spite of gloomy clouds such as in different ways overshadowed the lives of a singularly large proportion of the great authors in the century, produced a large amount of verse characterized alike by poignant appeal to the heart and by gorgeous and colorful word painting. Even more completely than Rossetti, William Morris (1834-96), was attracted by the purely picturesque quality of the Middle Ages; but he is more external, less of a mystic than the others of the group. His strongest point is his consummate ability to tell a smooth and flowing tale, in the manner of Chrétien de Troyes and others of the old French romancers, though with an occasional note of a purely modern pessimism. Greater poets, indeed, there have been; but from Chaucer to our own time, scarcely a greater story-teller in verse.

A similar tendency towards escape from the pressure on the one hand of the colorless materialism of dominant modern science, and on the other of the moral seriousness which characterizes the greater part of the English poetry of the last half century may be found in Swinburne. His mastery of technique, his power of creating marvelous effects of rhythm and melody, are unsurpassed; and the death of Tennyson and Browning left him alone to be the unquestioned chief of English singers, though his rebel attitude towards the social order robbed him of the glory of the laurel. The morbid excesses of his earlier work, conceived in the spirit of a decadent paganism, alienated many readers from him; but they have been succeeded by a noble presentation of higher motives, the characteristically English ones of a love of freedom and of the sea and of the innocent beauty of children. His very power over his instrument has tempted him at times to play tricks with it, to be careless of the sense in the intoxication of a riot of beautiful sounds and sights; but his touch is always that of a master. Promise for the future of English poetry has appeared in the work of Stephen Phillips, Francis Thompson, William Watson, John Davidson, and in the more serious verse of Kipling.

Macaulay has already been mentioned as a type of the English thought of his generation; but he may stand also as a representative in the nineteenth century of that school of historians of which the eighteenth produced such brilliant examples—the artistic school, who rested their claim to distinction more upon their manner than upon their matter. While his style is not perfect, while its recurrent antitheses, its emphasis upon the exceeding blackness of the black and the whiteness of the white, become wearisome after a while, yet he was undoubtedly a great historian—if history be the vivid and delightful narration of past events so presented as to make them fit into the writer's preconceived scheme of things. So was a later example of the method, James Anthony Froude (1818-94); but the new generation has learned (to adopt once more an overworked phrase) that, while such writing may be magnificent, it is not history. Carlyle was not so far wrong when he said that Macaulay had written his history to prove that Providence was on the side of the Whigs; and the deductive method, abandoned long before by science, still reigned in the work of the historian. It was succeeded by the truer method which now holds possession of the field—the calm, patient, minute investigation of the actual records of the period under study, and the presentation of results as found. This reaction, illustrated by the prodigious learning and critical judgment of such men as E. A. Freeman (1823-92), S. R. Gardiner (1829-1902), and William Stubbs (1825-1901), and largely associated with the University of Oxford, has at times, like all literary reactions, shown a tendency to go too far in the opposite direction and present a mere undigested mass of facts; but the scientific securing of them once established, the selection and composition which art requires will, it may be hoped, bring historical writing once more into the higher regions of literature.

In the province of pure literature, that which is cultivated for its own sake, much excellent work has been done by an increasing number of men, and, as already remarked, criticism has become a separate department. While no single

critic holds the supreme dictatorship of Matthew Arnold, a substantial gain has been made by the use of the comparative method, which treats literature not as an isolated phenomenon, but as part of a vast general movement. For adequacy of equipment, George Saintsbury (1845-) is probably the first of these later critics; but the appreciation of Edmund Gosse (1849-) and the refined versatility of Andrew Lang (1844-1912), the philosophic insight of Dowden (1843-1913) and Shafrin (1819-85), must have a word of mention. In definite contrast to these, who are men of letters pure and simple, stand the natural scientists and some later philosophers who value the written word only as a means of expression and diffusion for their thought; the names of Darwin (1809-92) and Tyndall (1820-93) and Huxley (1825-95), of Herbert Spencer (1820-1903) and John Morley (1838-) and Arthur Balfour (1848-), cannot be passed over in even a purely literary review, so great has been their influence on the general evolution of thought and hence of its expression.

But the novel has in the last generation so overshadowed other forms of literature as to justify its treatment in these closing paragraphs with the same approach to exclusiveness as the drama claimed in the Elizabethan period. It would have been both hopeless and profitless to attempt to enumerate with any fullness of characterization the vast multitude of novelists that the last century has produced, or even the better-known among them—in the earlier period Bulwer (1831-91) and Disraeli (1804-81) and Charles Reade (1814-84), Anthony Trollope (1815-82) and the Brontës (1816-55) and the Kingsley brothers (1819-76); and in more recent times Blackmore and Mrs. Oliphant and Mallock and Black and Mrs. Ward and "Lucas Malet" and especially Kipling, and a score of others whose names will occur to any reader. But there are three names which may fitly receive less summary treatment, because two of them stand at least, after a long diversified career, unquestionably at the head of their craft, and because the third by a beautiful and inspiring life and an intimate charm of personality revealed in every line of his work has also won a very special place of his own. They are singled out also, in accordance with the general scheme of this article, as typical of the attainment and the outlook in their kind of work. The first and possibly the greatest of them, George Meredith (1828-1909), is in some sense the successor of George Eliot—the successor in development, though, for actual chronology, he published his first book before hers appeared. We have already noted her work in the study of social questions and her portrayal of the characteristic mental temper of her day; it remains to call attention, for the connection of thought, to the ethical import of her novels, to her rigorous insistence on the reign of law in the development of moral character. Meredith, though he works not so much through individuals as through types, though his method is often elusive, deals mainly with the inevitable working out and consequence of one or another moral quality. His style is often called obscure, like that of Browning, with whom he has many analogies; but his marvelous insight into the springs of human action, his ripe philosophy, and his genial humor compensate the reader for any effort of attention.

To Meredith, man, his work in the world, his development of himself, is the centre of interest. To an equally great novelist, Thomas Hardy, man is but an insignificant and feeble creature, moving helplessly through a world controlled by gigantic forces, pitiless, implacable—a world conceived in a spirit not unlike that Æschylean gloom and awe of the forces of Nature and Fate which we saw to pervade the poetry of the pagan Saxons. Life to him is pure tragedy, relieved only by flashes of a grim irony as bitter as, though more resigned than, Swift's. His attitude expresses one aspect of the temper of the closing nineteenth century—its weariness of the insistent discussion of questions of right and wrong which so occupied its central period. A totally different means of escape, one offered with the light-heartedness of a child who breaks out from tedious lessons to play, is that of Robert Louis Stevenson (1850-94), the third of the authors chosen to lead to a conclusion. His style is noteworthy for its deliberate artistic finish and grace, qualities which he shared with a brilliant contemporary master of form, Walter Pater (1839-94). It is probable that his essays, in which he expresses a whole, courageous, and hopeful philosophy of life, will in the end hold a higher place than his fiction; but for the moment it will be well to direct the attention to the latter, which marks the rounding off of our survey of the nineteenth century with a return to the romanticism that began it, and reminds us once more of one of the chief functions of all literature, which is to lift us above the sordid atmosphere, the corroding cares of that "struggle for life" which modern science presents to us as our only occupation, into a brighter and more joyous world.

As a last word, certain tendencies that marked the close of the nineteenth and the opening of the twentieth century should be noted. First of all, there was a deepening interest in the drama, as shown by the more serious critical consideration—well represented in the work of William Archer—which it received, and by the demand for plays published in book form; witness the names of Barrie, Yeats, Synge, and Shaw. Barrie was conspicuous and popular by his stagecraft, his romantic fantasy, his grace, and his freshness of invention; Yeats and Synge were inspired by the old romance or the contemporary reality of Celtic Ireland. None of these, however, takes us into the main current of the dramatic activity of the time. It remained for Bernard Shaw to perform that service. In different ways Wilde and Pinero taught the playwright to come to close quarters with contemporary life and were in that regard Shaw's predecessors. But this brilliant and audacious innovator, following the bent of his own genius and stimulated by the best French drama of the day and by the plays of Ibsen, with their deft and fearless criticism of modern life, has given the English drama a new direction, has filled it with new ideas, seasoned it with mordant wit, and has afforded one more illustration of the potent influence of the mood and point of view of the Scandinavian dramatists. It is Shaw and his disciples, Granville Barker conspicuous among them, who exemplify the vital dramatic movement of their day. Another mark of the period in question is the reviving taste for poetry. The pleasure a growing public takes in the work, e.g., of Alfred Noyes, of John Masefield, of Herbert Trench, of Walter De la Mare,

and of A. E. Housman is evidence of this. Another evidence is afforded by the cordial reception given the poets of perhaps the most interesting literary movement of its time, the Irish literary revival, who, heard as a choir in the nineties of the last century, were still vocal in the twentieth, and among whom Yeats, Synge, Moira O'Neil, and "A. E." (G. W. Russell) may be mentioned.

In the fiction which belonged to the vital literature of the time the drift was away from static romance and aimlessly detailed realism, and set strongly towards the concrete and imaginative presentation of the social, ethical, and sentimental problems of the day as recognized by the intellectually conscious classes and especially as related to the readjustment of ideals necessitated by the development and spread of feminism. This tendency is clearly seen in the novels of H. G. Wells, John Galsworthy, and a group of minor novelists who follow in their steps.

Bibliography. For bibliographies of individual authors, see articles on those authors. More, *The Drift of Romanticism* (ib., 1913); Phelps, *The Beginnings of the English Romantic Movement* (Boston, 1893); Mrs. Oliphant, *Literary History of England in the Eighteenth and Nineteenth Centuries* (London, 1883); Minto, *Literature of the Georgian Era* (ib., 1895); Woodberry, *Makers of Literature* (New York, 1900); Saintsbury, *Essays in English Literature, 1780-1860* (London, 1st series, 1890; 2d series, 1895); Dowden, *The French Revolution and English Literature* (ib., 1897); Beers, *English Romanticism in the Nineteenth Century* (New York, 1901); Holman Hunt, *Pre-Raphaelitism and the Pre-Raphaelite Brotherhood* (2 vols., London and New York, 1906); Saintsbury, *Nineteenth Century Literature* (London, 1896); Dowden, *Studies in Literature, 1789-1887* (2d ed., ib., 1882); id., *New Studies in Literature* (ib., 1895); Stephen, *Hours in a Library* (3 vols., ib., 1874-79); Hutton, *Literary Essays* (ib., 1888); Harrison, *Early Victorian Literature* (ib., 1895); Brownell, *Victorian Prose Masters* (New York, 1901); Saintsbury, *Corrected Impressions* (London, 1895); Dawson, *Makers of Modern English* (New York, 1902); Sarrazin, *Poètes modernes de l'Angleterre* (Paris, 1885); Stedman, *Victorian Poets* (Boston, 1886); Brandes, *Main Currents of Nineteenth Century Literature* (Eng. trans., 3 vols., New York and London, 1901-02); Scudder, *Social Ideals in English Letters* (Boston, 1898); Chambers's *Encyclopedia of English Literature* (2 vols., Philadelphia, 1902-04).

ENGLISH MERCURY. See CHENOPodium.

ENGLISH OPIUM EATER. See DE QUINCEY, THOMAS.

ENGLISH PALE, also known as **IRISH PALE**, **THE PALE**, or **ENGLISH LAND**. That portion of Ireland brought under English rule before the complete conquest of the island. The name Pale was applied to the land until the fourteenth century, although "English land" was employed as early as the time of Edward I. These terms were used to distinguish the section of country around Dublin from the surrounding territories, which were called the "marches," or border lands. In 1366 the Statute of Kilkenny was passed, establishing the use of English law in the Pale and prohibiting intermarriage between English and Irish as well as the adoption of Irish manners and customs. The boundaries of the Pale were at no time definitely determined, but varied with the rise or decline of English power in Ireland and with the military activity of the Norman and Celtic chiefs in the interior. In 1515 the Pale extended from Dundalk, in County Louth, to Dalkey, 7 miles south of Dublin, a stretch of territory about 50 miles long, with an average breadth of 20 miles. In 1535, although the Pale was supposed to contain the counties of Louth, Meath, Kildare, and Dublin, the Irish plundered at the very gates of Dublin. Cromwell was led to subjugate the whole island by the rebellion of the Catholic gentry and their invasion of the Pale. The Pale was subject to the enactments of the Irish Parliament, and for a long time the English government with great difficulty maintained its hold upon it. The supremacy of the English crown in the

Pale was established by the enactment of the celebrated Poynings Law in 1494. Consult Joyce, *Concise History of Ireland* (New York, 1903). See IRELAND.

ENGLISH POETRY, SPASMODIC SCHOOL OF. An expression employed by the critics to designate a group of English poets midway in the nineteenth century. The group included Philip James Bailey, Alexander Smith, Gerald Massey, Sydney Dobell, and other minor poets. Swinburne was sometimes classed with them. In ridicule of their extravagance in theme and style W. E. Aytoun wrote a tragedy called *Firmilian* (1854), which, containing many passages of true poetry, rather missed the mark. See the separate articles on the poets here mentioned.

ENGLISH SNIPE. Wilson's snipe. See SNIPE.

ENGLISH SPARROW. See HOUSE SPARROW.

ENGLISH VERSIONS. See BIBLE.

ENGORGEMENT. See MEGRIMS.

ENGRAFTING. See GRAFTING.

ENGRAILED, *en-gräld'* (from Fr. *engrêler*, to engrail, from *en*, in + *grêl*, OF. *gresle*, hail, from OHG. *grîoz*, Ger. *Gries*, AS. *grêot*, Eng. *grit*, gravel). A term in heraldry (q.v.) denoting a line composed of a series of concave semicircles.

ENGRAVER BEETLE. See BARK BEETLE.

ENGRAVING. The art and the process of making incisions in a hard surface, removing a part of the material. The term is applied also to the engraved block or metal plate, but not properly to the impression made therefrom, the proper designation of which is print (q.v.). Engraving may be divided into that which is done for its own sake, to show in contrast with the smooth surface around, and that which is done for the sake of the prints which may be taken from it. If an engraved surface be covered with ink or wet color, paper or the like pressed upon it will take the impression of the parts remaining untouched, while the hollowed out (engraved) parts will not print off. This is called relief (q.v.). Its most important variety is *line engraving* (q.v.). But if the ink or color be forced into the hollowed parts, while the smooth part is wiped clean, the paper, usually wet, will draw from the engraved lines and spaces the ink which they have contained, while the rest of the paper is left white. This process is properly called *line engraving* (q.v.), sometimes also *copperplate engraving*, because this metal was generally used in the process. If the lines are eaten into the plate by means of an acid, the process is called *etching* (q.v.); if the surface is merely roughened without incision of lines, it is called *mezzotint* (q.v.).

There is still to be mentioned that engraving which is done with the purpose of stamping a soft substance, thereby leaving a relief impression, as in the case of seals. The objects represented are reversed in the engraving. This is the process usually called *intaglio* (q.v.), and it is especially applied to gems (q.v.). Such *intaglios*, however, have frequently been cut for their own intrinsic beauty without intention for use as seals.

Engraving of the kind first above named, viz.; that done for the effect produced on the surface engraved, is seen in its simplest form in the rock carvings of primitive peoples. It is also

seen in the inscriptions of the ancients, particularly of the Greeks and Romans, which were carved not only to read but for their decorative effect. This is also true of inscriptions on tombstones previous to the nineteenth century, the ornamentation and lettering of which are often carved with the utmost delicacy. But all this material is more properly designated carving (q.v.). It is otherwise with the engraving on bronze and steel plate, armor, etc., such as the Orientals, especially the Chinese and Japanese, delighted in. These are true engravings of the most subtle technique. Modern silverware, both of European and American manufacture, is often engraved with fine decorative effect.

But the usual use of the term "engraving," and the one with which we are concerned, is in connection with prints. The four principal processes are treated under the headings *WOOD ENGRAVING*, *LINE ENGRAVING*, *ETCHING*, and *MEZZOTINT*, to which the reader is referred. Certain other processes of engraving receive special treatment, such as *DRY POINT*, *AQUATINT*, *MANIÈRE CRIBLÉE*, *STIPPLE*, and *SOFT-GROUND ETCHING*. Mixed processes, such as a combination of etching with line engraving or etching with mezzotint, are described under the above headings. For a remarkable example of a mixed process, see *LIBER STUDIORUM*. Important technical terms connected with engraving are treated under such special headings as *BURIN*, *PROOF*, *PRINT*, ETC. *Lithography* (q.v.), although a process of printing, is not properly engraving, because no lines are incised. Photographic processes of engraving are treated under the heading *PHOTO-ENGRAVING*.

History. The history of the different processes of engraving is described at length under the appropriate headings; suffice it here to say that wood engraving for the purpose of printing first became an art in the early years of the fifteenth century, and that line engraving developed in connection with the art shortly before the middle of the same century. Both seem to have first appeared in Germany, where engraving was frequently practiced, but they appeared shortly afterward in Italy. Both processes reached their highest development during the early part of the sixteenth century in the works of Albrecht Dürer, the world's greatest and most influential engraver. Up to this time engraving was an original art, in the same sense that painting was, and the term "painter engraver" was usually applied to artists of this description. But during the latter sixteenth century engraving began to be used to reproduce paintings; Marc Antonio, the engraver of Raphael's works, leading the way. This practice continued throughout the later sixteenth, seventeenth, and eighteenth centuries, greatly to the detriment of engraving. Meanwhile etching, which, by the nature of its technique, was particularly adapted for original work, attained its highest development in Holland in the prints of Rembrandt. In the early nineteenth century Thomas Bewick, by a new technique—the use of the "white line"—revolutionized wood engraving which thereafter became the principal medium used in illustration. The American wood engravers, working since 1875 for the prosperous illustrated magazines, achieved remarkable results in the reproduction of paintings and even in original portrait and landscape work; but the recently

"ADORATION OF THE MAGI"
FROM AN ENGRAVING BY ALBERT DÜRER

perfected photographic processes of printing tend more and more to deprive wood engraving of its uses for illustration. Line engraving is now practically an obsolete art. Etching, on the other hand, although it declined in the eighteenth century, achieved a remarkable development in the nineteenth, especially through the influence of the American Whistler and the Frenchman Méryon. This excellence has lasted to the present time, both in Europe and the United States.

Bibliography. Of general catalogues covering special epochs the most celebrated is Bartsch, *Le peintre-graveur* (21 vols., Vienna, 1803-21), reprinted (Leipzig, 1854), and supplemented by Passavant, *Le peintre-graveur* (6 vols., Leipzig, 1860-64). The French engravers were included in Robert-Dumesnil, *Le peintre-graveur français* (8 vols., Paris, 1835-50); the Flemish and Dutch in Van der Kellen (ed.), *Le peintre-graveur hollandais et flamand* (Utrecht, 1873). The more recent artists are treated in Hippert and Linnig, *Le peintre-graveur hollandais et belge du XIXe siècle* (Brussels, 1874-79); Beraldi, *Les graveurs du XIXe siècle* (12 vols., Paris, 1885-92). The engravers and their works are also treated in such general biographical works as Bryan, *Dictionary of Painters and Engravers* (rev. ed., 5 vols., New York, 1903-05), and, best of all, in Thieme-Becker, *Allgemeines Lexikon der bildenden Künstler* (Leipzig, 1907-).

Other good treatises on the subject are: Fielding, *Art of Engraving* (London, 1840); Duplessis, *Les merveilles de la gravure* (Paris, 1871; Eng. trans., London, 1871); Baker, *American Engravers and their Works* (Philadelphia, 1875); Willshire, *Introduction to the Study and Collection of Ancient Prints* (London, 1877); Hamerton, *Graphic Arts* (ib., 1882); Lostalot, *Les procédés de la gravure* (Paris, 1882); Delaborde, *La gravure* (ib., 1882), trans. by R. A. M. Stevenson, with a chapter on English engraving by William Walker, as *Engraving: Its Origin, Processes, and History* (New York, 1886); Duplessis and Bouchot, *Dictionnaire des marques et monogrammes* (Paris, 1886); Wedmore, *Fine Prints* (London, 1897); Singer and Strang, *Etching, Engraving, and Other Methods of Printing Pictures* (ib., 1897); Lipinmann, *Engraving and Etching* (Eng. trans., ib., 1906); Whitman, *The Print Collectors' Handbook* (ib., 1907); Weitenkamp, *How to Appreciate Prints* (New York, 1908); Carrington, *Prints and their Makers* (ib., 1912). For modern commercial processes, see Baker, *Dictionary of Engraving* (Cleveland, 1908).

HISTORY: The most important general work is Duplessis, *Histoire de la gravure en Italie, en Espagne, en Allemagne, dans les Pays-Bas, en Angleterre, et en France* (Paris, 1888). Briefer historical treatises are Hind, *A Short History of Printing and Engraving* (London, 1908), and Austin, *The History of Engraving* (ib., 1909), a good concise manual extending to the time of Bewick. For engraving in the different countries, see Lützow, *Geschichte des deutschen Kupferstichs und Holzschnittes* (Berlin, 1901); Dilke, *French Engravers and Draughtsmen of the Eighteenth Century* (New York, 1902); Nevill, *French Prints of the Eighteenth Century* (London, 1908); Thomas, *French Portrait Engraving of the Seventeenth and Eighteenth Centuries* (ib., 1910); Gosse, *British*

Portrait Painters and Engravers of the Eighteenth Century (New York, 1905); Salaman, *The Old Engravers of England* (London, 1907). The best and most comprehensive publication on recent engraving is Lützow, *Die vielfältigen Künste der Gegenwart* (3 vols., Vienna, 1893)—the part dealing with American engraving is by S. R. Koehler; Weitenkamp, *American Graphic Art* (New York, 1912). For the literature on special branches of engraving, see the bibliographies of WOOD ENGRAVING; LINE ENGRAVING; ETCHING; MEZZOTINT; ETC.

The most trustworthy collection of reproductions of prints from metal engravings is that of Armand-Durand. Other collections are *The British Museum Reproduction of Prints* (London, 1882 et seq.); and Hirth, *Kulturgeschichtliches Bilderbuch aus drei Jahrhunderten* (6 vols., Leipzig, 1882-90).

ENGROSSING (OF. *engrossir*, from ML. *ingrossare*, to engross, from Lat. *in*, in + *grossus*, large). The crime of buying up standing corn or victuals at wholesale (Fr. *en gros*) in order to sell them again at retail (known as regrating) in the same market at an enhanced price. It corresponds closely to the modern practice of making a "corner" in one of the necessities of life. These practices were regarded as criminal in most countries before the laws by which trade is regulated were properly understood. In England they were forbidden by various statutes, from the time of Edward VI to that of Queen Anne. It was found, however, that engrossing was not only a statutory but a common-law offense, and a prosecution for it in the latter character actually took place in the nineteenth century. The Act 7 and 8 Vict., c. 24, abolishing the offenses of forestalling, regrating, and engrossing, was consequently passed. Besides declaring that the several offenses of badgering, engrossing, forestalling, and regrating be utterly taken away and abolished, and that no information or prosecution shall lie either at common law or by virtue of any statute, either in England, Scotland, or Ireland, this statute also repeals a host of earlier enactments in restraint of trade, which had been omitted in the statute in the time of George III, above referred to. In the United States much litigation has arisen in recent years respecting the combinations for engrossing and the necessities of life. See COMBINATIONS; MONOPOLY; RESTRAINT OF TRADE; TRUSTS. See also CONTRACT; FORESTALLING; REGRATING. Consult the commentaries of Blackstone, Stephen, and Kent, and the authorities under CRIMINAL LAW and POLITICAL ECONOMY.

The term also denotes the writing of a statute or other legal instrument *en gros*, or in a fair, round hand. It is, in the United States, often applied to the final and official draft of a statute.

ENGUINEGATTE. See GUINEGATE.

ENGUION, or **ENGUIM**, or **ENGYON.** See GANGI.

EN'HARMONIC (from Gk. *ἐναρμονικός*, *enarmonikos*, in harmony, from *ἐν*, *en*, in + *ἀρμονία*, *harmonia*, harmony, from *ἀρμός*, *harmos*, a joining, from *ἀείν*, *arein*, to be about to join). 1. In music, a term denoting a difference in the degrees, but not in the pitch of tones, C# and Db, F# and Gb. Correctly speaking, there is or ought to be a difference; but on keyed instruments, such as the organ and pianoforte, there can be none, as the same key serves for both sharps and flats, while with a just equal tem-

perament the ear is no way offended. An enharmonic change, as from C# to Db, or vice versa, is often of practical value to the musician, enabling him, e.g., to avoid writing in a key containing an unwieldy number of sharps or flats. 2. In Greek music, a tetrachord of which the first two steps were quarter steps and the third a major third: e, e#, f, a.

ENHUBER, en'hoo-bēr, KARL VON (1811-67). A German genre painter and illustrator. He was born at Hof, Bavaria, and was educated at the Munich Academy. His pictures, distinguished by a lively, if somewhat ponderous, sense of humor, portray German folk life—usually that of the peasants of Upper Bavaria. Among the best are: "The Partenkirchen Fair," which first gained him celebrity; "The Interrupted Card Party"; "The Curver"; "Munich Burgher Guardsman" (National Gallery, Berlin); "Court Day in Bavaria" (Darmstadt Gallery); "Wood Carver in his Shop" (New Pinakothek, Munich). His most important graphic work was the illustrations to Melchior Meyr's *Stories of the Ries*, six plates of which are in the Leipzig Museum.

ENID. The wife of Geraint, and a model of marital devotion. She appears in the *Erec and Enide* of Chrestien de Troyes and in Tennyson's *Idylls of the King*.

ENID. A city and the county seat of Garfield Co., Okla., 88 miles by rail west by north of Oklahoma City, on the Atchison, Topeka, and Santa Fe, the Chicago, Rock Island, and Pacific, and the St. Louis and San Francisco railroads (Map: Oklahoma, D 2). It is in a rich agricultural region and is one of the largest poultry centres west of the Mississippi, shipping in 1913 more than \$3,000,000 worth of poultry and eggs. The industrial establishments include planing and flour mills, foundry and machine shops, boiler works, a brick plant, and manufacturing of corn seeders and binders, steel posts, rugs, candy, etc. Enid contains the Phillips University, St. Francis Institute (Catholic), College of Fine Arts, a State institution for the feeble-minded, a Carnegie library, a fine high school, Federal and courthouse buildings, two parks, and two hospitals. The city adopted the commission form of government in 1909. It owns its water works. Pop., 1900, 10,087; 1910, 13,799; 1914 (U. S. est.), 18,209.

ENIMÁGAN. A linguistic stock of South American Indians in the northern Gran Chaco, the "Maskoi" group of Koch-Grünberg. The chief tribes are the Enimá, Guaná, Sanapana, Sapuki, etc., "Lengua." Consult writings of Boggiani, Hawtrey, Kersten, Koch-Grünberg, Lafone-Quevedo, Schuller, etc.

ENKHUIZEN, ênk'hoi-zen. A seaport of the Netherlands, in the Province of North Holland, situated on the west shore of the Zuider Zee, about 37 miles northeast of Amsterdam (Map: Netherlands, D 2). Its most important public building is an elegant town house with a lofty tower, and mural decorations by Johan van Neck. In the seventeenth century it had a population of upward of 40,000 and sent a fleet of 100 vessels to the herring fisheries, but the herring trade has died away. Its chief industries now are ropemaking and shipbuilding. The town is the birthplace of the painter Paul Potter. Pop., 1901, 6865; 1911, 7748.

ENLIGHTENMENT, PHILOSOPHY OF THE.

A term applied to the more popular philosophy of the eighteenth century because of its protest against superstition and its attempt to establish all accepted belief and all rules of practical life upon reason. The term includes the empiricism and deism of the English thought of the eighteenth century, the empiricism and sensualism of the French thought, and the rationalism of the German thought. It was characterized largely by individualism (q.v.). The movement began in the seventeenth century with Locke in England, with Pierre Bayle in France, and with Leibnitz in Germany. But such men as Hume, the English deists, Voltaire, Rousseau, Condillac, the encyclopædists, Reimarus, Mendelssohn, Eberhard, and Lessing, are usually referred to under this title, represented in German by *Aufklärung* and in French by *éclaircissement*. Thomas Paine in his *Age of Reason* and Benjamin Franklin are its best-known American representatives. Sometimes the age of the Greek sophists is called "the Greek enlightenment" on account of its similarity in spirit to the modern period referred to. Greek sophistry in its best days was a rebellion against tradition and an attempt to intellectualize life. Consult the histories of philosophy by Höffding, Windelband, Ueberweg, and Kuno Fischer; also Hibben, *The Philosophy of the Enlightenment* (New York, 1910).

ENLISTMENT. The voluntary contract by which a citizen becomes an enlisted man and joins the military or naval forces of the country. In the United States and Great Britain voluntary enlistment takes the place of conscription, or compulsory service, used by all the other Great Powers as the method of securing men for the army and navy. (See CONSCRIPTION.) In the United States any male citizen, or person who has legally declared his intention to become a citizen, may enlist in the army if above the age of 21 and under 35 years of age, able-bodied, free from disease, of good character and temperate habits. No man is eligible who has been convicted by civil power of felony or served time in a reformatory, jail, or penitentiary. He must speak, read, and write the English language. The physical examination of recruits is conducted in accordance with the authorized manual for the examination of recruits. After enlistment, recruits are assigned to regiments or other organizations by the adjutant general of the army under the direction of the Secretary of War. The recruiting service is under the management of the adjutant general, and is a branch of the adjutant general's department. Recruits have to conform to certain standards of build and physique, determined generally by the branch of the service for which the man is enlisted. The term of enlistment is "for a period of seven years in active service and in the army reserve." Active service in the army is for either three or four years, the remaining four or three years being in the army reserve, where no military duty is required, and in which the soldier practically resumes the status of a civilian, being subject to military service only in case of war. Additional pay for all grades is allowed for reenlistments within three months of expiration of preceding enlistment. In the English army, under the Law of 1907, which discontinued the militia and established a special reserve, the military forces consist of the regular army and the territorial army. The regular army is composed of the permanent

army, the army reserve, and a special reserve. Duration of service in the permanent army is 12 years, of which three, five, or nine years may be in the reserve. All good-conduct men may serve a total of 21 years, with pension. Ordinarily in the colonies and in India the service is from 12 to 16 years. The special-reserve enlistment is for six years. The territorial army enlists for four years. See RECRUITMENT.

In the naval service of the United States all men are enlisted to serve for four years, which may be extended by the Secretary of the Navy for one, two, three, or four years. Upon reenlistment they are entered continuous-service men, and are given a certificate of continuous service, which entitles them to an increase of monthly pay. This increase is given for each term of four years served if the reenlistment takes place within four months of discharge. Failure to enlist within four months causes a forfeiture of all rights and privileges due to previous service.

ENNA, or **HENNA**. In antiquity, the name of a town in Sicily, now Castrogiovanni, situated near the centre of the island, wherefore it was called the navel of Sicily. It was one of the seats of the cult of Demeter, and near it tradition placed the carrying off of Persephone by Pluto. See CERES; PROSERPINA; CASTROGIOVANNI.

ENNA, AUGUST (1860-). A Danish composer, born at Nakskov on the island of Laaland. He was entirely self-taught and in 1880 joined a traveling troupe as violinist. The next year he settled in Copenhagen, where he earned his living as a violinist, and produced an operetta, *A Village Tale*. In 1883 he became conductor of a small provincial company. His compositions finally attracted the attention of Gade, who enabled him to study one year in Germany (1888-89). The extraordinary success of his opera *The Witch* (1892) made him famous, and the work immediately found great favor in Germany. His other operas are: *Oléopatra* (1894); *Aucassin et Nicolette* (1896); *Lamia* (1900); *Id and Little Christina* (1902); *The Death of Antony* (1903); *The Golden Slipper of St. Cecilia* (1904); *Gloria Arsena* (1913). While all have met with more or less success, none approach *The Witch*. He also wrote a legend for soli, chorus, and orchestra, *A Mother's Love*, and a violin concerto.

ENNEACRUNOS, ἐννέα-κρῶνός ('Ennéa-krounos, having nine springs, from ἐννέα, ennea, nine + κρῶνός, krounos, spring). The name of a famous fountain at Athens. See ATHENS, *Archæology*.

ENNEKING, JOHN JOSEPH (1841-). An American landscape painter, born at Minster, Ohio. He was educated at Mount St. Mary's College, Cincinnati, served in the Civil War, and later devoted himself to painting. He studied in New York, Boston, Munich, and in Paris under Bonnat and Daubigny. Among his best pictures are: "November Twilight"; "Summer Twilight"; "Indian Summer"; "The Coming Storm"; "Springtime"; and "Autumn in New England" (Worcester Museum).

ENNEMOSER, ἐννεμόζερ, JOSEPH (1787-1854). A German medico-philosophic writer, born at Hintersee, in the Tirol. He pursued his studies under great difficulty for want of means and because of interruption by war. He fought with the Tyrolese against the French in 1809 and also fought against Napoleon in 1813-14.

He received his degree in medicine in Berlin in 1816. In 1819 he was made professor of medicine at the new University of Bonn, where he lectured on anthropology and also therapeutics and pathology. After practicing for a time as a physician at Innsbruck, he went to Munich in 1841, and there obtained a great reputation by the application of hypnotism (then called magnetism) as a curative agency. His principal work, published in Leipzig in 1819, was entitled *Der Magnetismus in seiner geschichtlichen Entwicklung* (1819). Among his other writings are: *Historisch-psychologische Untersuchungen über den Ursprung und das Wesen der menschlichen Seele* (1824); *Anthropologische Ansichten zur bessern Kenntnis des Menschen* (1828); *Der Magnetismus im Verhältnis zur Natur und Religion* (1842); *Der Geist des Menschen in der Natur* (1849); *Was ist die Cholera?* (2d ed., 1850); *Anleitung zur mesmerischen Praxis* (1852). The first volume of his *Geschichte des tierischen Magnetismus* (1844) was translated into English by William Howitt (1854) and entitled *History of Magic*.

ENNES, ἐννέση, ANTONIO (1848-1901). A Portuguese dramatist, born in Lisbon. He was long brilliantly active as a journalist, in 1886 was appointed chief librarian of the National Library, and in 1890 Minister for Marine and the Colonies. His chief drama is *Os Lazaristas* (1874), presented with marked success in Portugal and Brazil. His *Un divorcio* appeared in 1879 and was translated into French and Italian.

EN/NIS. A municipal borough, capital of Clare County, Ireland, and a port on the Fergus, 25 miles west-northwest of Limerick (Map: Ireland, B 6). It has a Roman Catholic college, the ruins of a Franciscan abbey, founded in 1194 by Donnell O'Brien, King of Munster, and a colossal statue and monument to Daniel O'Connell, erected in 1865. Near the town is Ennis College, founded by Erasmus Smith. Ennis manufactures flour, and brewery and distillery products, has a valuable limestone quarry, and some trade in grain. Pop., 1901, 5093; 1911, 5472.

EN/NIS. A city in Ellis Co., Tex., 34 miles south of Dallas, on the Houston and Texas Central and the Texas Midland railroads (Map: Texas, D 3). It is in an agricultural and stock-raising region and has cotton compresses, cotton gins, cottonseed-oil mill, railroad shops, flouring mill, etc. Ennis adopted the commission form of government in 1914. Its water works are the property of the municipality. Pop., 1900, 4919; 1910, 5669.

EN/NISCOR/THY. A market town in Wexford County, Ireland, on rising ground on the Slaney, 77½ miles south by west of Dublin (Map: Ireland, E 7). The Slaney is here tidal and navigable for barges and flows through a fertile and beautiful valley. Its well-preserved castle, founded in 1176 by Robert le Gros, one of the early Anglo-Norman invaders, is of great interest. It has flour mills and breweries, and there is some tanning and distilling, as well as woolen manufacture. Pop., 1901, 7667; 1911, 7991. Enniscorthy was captured in 1649 by Cromwell, and at Vinegar Hill, in the vicinity, General Lake, on June 21, 1798, defeated the Irish rebels, who had stormed and burned the town a few days previously.

ENNISKILL/LEN, or **INNISKILLING** (Ir. *Inis Cethlenn*, island of Cethlenn, an ancient

queen of Ireland). A municipal borough, market town, and the capital of County Wick, Ireland, about 75 miles west-southwest of Belfast (Map: Ireland, D 3). It is beautifully situated on the Erne, the greater portion on an isle in the river between upper and lower Loughs Erne. Among its buildings are large barracks, an infirmary, and the town hall, in which are kept flags captured at the battle of the Boyne. It has tanneries, cutlery works, straw-hat works, and markets for butter, pork, and flax. Pop., 1901, 5412; 1911, 4847. Enniskillen received its first charter in 1612. In 1689 a detachment of troops of William III successfully defended the place against a superior force of James II. Some of its defenders subsequently formed a cavalry regiment and organization, which was continued and still bears the name of the Enniskillen Dragoons.

ENNIUS, QUINTUS (239–169 B.C.). An early Roman poet, the father of the Roman epos. (See **EPIC POETRY**; **LATIN LITERATURE**.) He was born at Rudiae in Calabria and was probably of Greek extraction. He is said to have served in the Roman wars and to have risen to the rank of a centurion. In Sardinia he became acquainted with Cato the Elder and came with him to Rome, when about the age of 38. Here he gained for himself the friendship of the most eminent men, among others Scipio Africanus the Elder, and attained the rank of a Roman citizen. He supported himself by instructing some young Romans of distinguished families in the Greek language and literature, his accurate knowledge of which explains the influence he had on the development of the Latin tongue. His remains were interred in the tomb of the Scipios, and his bust was placed among those of that great family. Ennius tried his powers in almost every species of poetry; although his language and versification are at times rough and unpolished, these defects are fully compensated for by the energy of his expressions and the fire of his poetry. He was especially successful in tragedy and epic. His epic poem, the *Annales*, in 18 books, dealt with the history of Rome from the time of Aeneas to his own day. By reason of this poem, long highly esteemed, the Romans called Ennius the father of Roman poetry; Vergil owed much to it. Of his tragedies, comedies, satires, and *Annales* only fragments remain. These have been collected and edited by Vahlen (Leipzig, 1854; 2d ed., 1903), Müller (St. Petersburg, 1885), and in Postgate's *Corpus Poetarum*, vol. i (London, 1893). The fragments of his tragedies were collected by Ribbeck in his *Tragicorum Romanorum Fragmenta* (3d ed., Leipzig, 1897). Consult: Sellars, *Roman Poets of the Republic* (3d ed., Oxford, 1889); Mackail, *Latin Literature* (New York, 1896); Duff, *A Literary History of Rome* (London, 1909). For an elaborate account of his life and of his influence on later writers, consult "Prefatio" to Vahlen, *Ennianæ Poësis Reliquiæ* (Leipzig, 1903), and the review of that discussion by Knapp, in an article on "Vahlen's Ennius," in *American Journal of Philology*, vol. xxxii (New York, 1911).

ENNO'DIUS, MAGNUS FELIX (c.473–521). A bishop of Ticinum (Pavia). His writings suggest that he may have been trained for the profession of rhetoric. He took deacon's orders at about the age of 20. In 514 Pope Hormisdas appointed him Bishop of Ticinum. He was twice sent as Ambassador to Constantinople (515

and 517), but his efforts to heal the schism then existing between the Eastern and the Western church were fruitless. In his doctrinal views Ennodius inclined towards semi-Pelagianism. He is best known as a champion of the papacy, especially in its claim to exemption from all human jurisdiction. This claim he was the first to advance, in his apology for the Synodus Palmaris (501 A.D.), held for the purpose of deciding between two rivals for the office of Roman bishop. The synod refused to pronounce a decision on the question, and Ennodius defended its action on the ground that the Pope was not answerable to a council, or in fact to any earthly tribunal, for God had reserved the popes for judgment by Himself alone.

Among Ennodius' writings are a life of Epiphanius, his predecessor at Ticinum; an autobiography of his early life, entitled *Eucharisticum*; many letters; a few hymns, which were never widely used; and some secular poems, which are in part thoroughly pagan. The old editions of his works (1509 and 1611, the latter reprinted by Migne, in *Patrol. Lat.*, vol. lxiii) have been superseded by those of Hartel, in *Corpus Scriptorum Eccles. Lat.*, vi (Vienna, 1882), and Vogel, in *Monum. Germ. Auctorum Antiquiss.*, vii (Berlin, 1885). Consult: Ebert, *Geschichte der Literatur des Mittelalters*, i (Leipzig, 1889); Hasenstat, *Studien zu Ennodius* (Munich, 1890); Teuffel, *History of Roman Literature* (London, 1892).

ENNS, or **ENS**, *éns*. A river of Austria, rising south of Radstadt, in the Noric Alps, and flowing east-northeast to the northern part of Styria to Hieflau, then turning and pursuing a sinuous northerly course through Upper Austria, emptying into the Danube near Mautausen (Map: Austria, D 2). Its total length is about 100 miles, only 20 of which are navigable for large boats. Through part of its course it forms the boundary between the provinces of Upper and Lower Austria. It becomes navigable for small river craft some distance below Hieflau. Of the large number of towns and villages on its banks, Steyr is the most important.

E'NOCH (Heb. *Hanok*). According to Gen. iv. 17–18, Enoch is the son of Cain and father of Irad, whereas in Gen. v. 18 he is the son of Jared. Some scholars consider Gen. iv as a relic of an ancient legend which endeavored to trace, after the fashion of folklore, the origin of civilization, or rather the Canaanitish culture, and ascribed some important feature of this civilization to Enoch. In Gen. v Enoch is said to have lived 365 years and walked with God, after which he was no more, "for God took him" (verse 24), a phrase that has been understood to mean that he was "translated," or carried bodily to heaven. Babylonian legends in which we encounter such "translations" have been thought to offer a partial explanation at least of the Enoch narrative. In the Gilgamesh epic Ut-napishtim, the hero of the deluge, is transported to the gods, and Gilgamesh himself, the hero of the epic, who is a semi-mythical character, also appears to have been translated. The number 365 adds weight to the supposition that Enoch was originally a solar deity like Gilgamesh, who from a god became a hero. Whether the name Enoch itself reverts to a Babylonian prototype cannot yet be determined, though there is some connection, without doubt, between the list of 10 patriarchs in Gen. v and

the 10 antediluvian kings mentioned by Berosus in his history of Babylonia, and also in a Sumerian text discovered by Poebel and published by him in vol. vi of the *Babylonian Publications of the University of Pennsylvania* (Philadelphia, 1913). The translation of Enoch, which bears a great part in Jewish and early Christian theology, is mentioned in Eccles. xlv. 16, xlix. 14, and also in Heb. xi. 5. From the fact that Enoch, like Elijah, does not die, but is transported to heaven, the apocalyptic literature naturally connected itself with his name. But the other side of Enoch, as a promoter of civilization, was not lost sight of. To the later Jews Enoch was the inventor of writing, arithmetic, and astronomy; and this view was adopted by the Mohammedans, by the Christians, and by the pagans of Harrañ, who identified him with Hermes Trismegistus. Consult Chwolson, *Die Ssabier und der Ssabismus*, vol. i, pp. 627 ff. (Leipzig, 1856), and Schmidt, *The Original Language of the Parables of Enoch*, p. 331 (Chicago, 1908). See ENOCH, BOOKS OF.

ENOCH, BOOKS OF. The statement in Gen. v. 24 that "Enoch walked with God, and was not, for God took him," interpreted as referring to his translation, made it natural that, in an age favorable to the production of apocalyptic literature, books should appear claiming the authority of the mysterious patriarch who enjoyed unrivaled opportunities of moving about in celestial realms, learning astronomical facts, observing the punishments and rewards meted out to men and angels, reading the tablets of destiny, and foreseeing the triumph of good in the world. How extensive the Enoch literature once was is not now known, but there are indications in ancient quotations that some parts of it have not yet been recovered. What is really a little collection of such books has been found in the Ethiopic, and one of these almost complete in the Greek, while a different book has been discovered in the Old Slavonic. It is customary to speak of the former as Ethiopic Enoch and the latter as Slavonic Enoch.

Ethiopic Enoch. Copies of this work were seen in Europe by Pico della Mirandola and Guillaume Postel long before it was discovered in Abyssinia by James Bruce in 1769. From one of the manuscripts brought to England by him Laurence published the Ethiopic text in 1838; Dillmann used five manuscripts in his edition of 1851, Flemming 15 in his edition of 1902, and Charles 23 in the last edition of 1906. Twenty-nine manuscripts were used by Charles in his translation of 1912. None of these is earlier than the sixteenth century; even the older group does not inspire the greatest confidence, and all manuscripts have evidently suffered much at the hands of copyists. The Ethiopic work is divided into five books. These seem to have been the only Enoch books known in the Abyssinian church. How the Greek version was constituted we do not know. Some copies of it may have contained "The Secrets of Enoch," preserved in Slavonic; whether any of them contained "The Parables of Enoch" is doubtful; various books may have circulated separately, and there is no evidence that any Greek manuscript was divided into five books. Since the Parables were introduced as "the second vision that Enoch saw," some Ethiopic editor naturally made them follow book i. The whole work was divided by Dillmann into 108 chapters; a manuscript was subsequently found

exhibiting the same division. *Book i* (chaps. i-xxxvi) deals with the fall of the angels, and the journey of Enoch through the earth in the company of an angel by whom he is initiated into the secrets of nature. Sin in the world is said to have been caused by the lust of the angels. Hence they were doomed to destruction, and in addition the deluge was sent to complete the first judgment of the world. Through the evil spirits, born of the children of the angels and the daughters of men, sin continued in the world after the deluge. A final judgment is therefore needed. This will take place on Mount Sinai, and angels, demons, all the godless, and all classes of Israel, with one exception, will be raised from the dead and receive their reward. The wicked will be cast into Gehenna, the righteous will behold their punishment, God will establish His kingdom in Jerusalem, the Gentiles will be converted, and the just will enjoy the greatest material blessings, eating of the tree of life, and begetting 1000 children. Of the Greek version of this book fragments have been preserved in Syncellus, viz., vi-x, 14, xv, 8-xvi, 1, and viii, 4-ix, 4 in a duplicate form, and the larger part of the book in manuscripts discovered at Akhmim in 1886-87, viz., i-xxxii, 6, and xix, 3-xxi, 9 in a duplicate form. The Syncellus fragments represent a somewhat better translation. *Book ii* (chaps. xxxvii-lxxi) contains, after an introduction (xxxvii), three parables (xxviii-xliv, xlv-lvii, and lviii-lxix) and two appended sections (lxx and lxxi). It holds a unique place in the Enoch literature by the close similarity of its Messianic ideas to those found in the New Testament. The Messiah is preëxistent, sits on the throne of God, possesses universal dominion, all judgment is committed unto Him, He slays the wicked by the word of His mouth, His kingdom is eternal, and He will dwell among the elect in a new heaven and a new earth. But the text has suffered greatly from interpolations, and it is extremely difficult to determine what its original form may have been. Chaps. lx, lkv-lxix, 25 come from a Noah Apocalypse, and xlix, 1-2a, liv. 7-lv, 2 probably have been derived from the same source. The "son of man" sections also appear to be interpolations—some of them Jewish, some Christian. *Book iii* (chaps. lxxii-lxxxii) treats of astronomy and the phenomena of the seasons. *Book iv* (chaps. lxxxiii-lc) describes the course of history from the beginning unto the end in visions, the leading actors appearing as animals, for the most part easily recognizable. There will be a last struggle between Israel and its enemies; then God will appear, the hostile army will be swallowed up by the earth, the wicked shepherds and the fallen angels will be punished; God will set up a new Jerusalem, the Gentiles will be converted and serve Israel, the dispersed Jews gathered together, the righteous dead raised to life again, and, finally, a ruler will come forth from the community, and all the righteous will be transformed into his likeness. A Vatican manuscript contains a fragment of the Greek version, consisting of lxxxix, 42-49. *Book v* (chaps. xci-cviii) contains a series of admonitions by Enoch to his children, prophecies of the final judgment, and assurances to the righteous of a life in companionship with the hosts of heaven. Chap. cv seems to be an addition; in the last verse the Lord promises: "I and my

Son will be with them"; chaps. cvi-cvii are taken from the Book of Noah. A Latin fragment, published by James (*Texts and Studies*, ii, 1893), contains cvi, 1-18, much shorter and yet with additional material, giving an idea of how different a book of this kind in the Latin version may have been from the text preserved in Abyssinia. Chap. cviii is another addition intended to encourage the righteous to hope in spite of the delay in the coming of the kingdom.

As to the original language of the Ethiopic Enoch, the idea occasionally expressed in the past that it was Greek has no defenders at present, all competent judges agreeing that it is likely to have been either Hebrew or Aramaic. Three scholars have examined the question more extensively and published their conclusions. Halévy in 1867 maintained that the entire work was written in Hebrew; Schmidt in 1908 gave reasons for thinking that the various books, and particularly the Parables, were written in Aramaic; and Charles in 1913 favors Aramaic for chaps. vi-xxxvi and somewhat less positively for book iv, but Hebrew for the rest. In view of the different origin and date of the five books it is not impossible that some were written in Hebrew and others in Aramaic. Charles thinks that the Maccabæan struggle, like similar movements for independence, caused a revival of the national language, and that consequently, while Aramaic might be used in book i, which he considers pre-Maccabæan, Hebrew is more likely in the later books ii, iii, and v. But Jesus Siracides wrote in Hebrew c.180 B.C., the author of Daniel vii in Aramaic after the Maccabæan uprising had begun (see DANIEL, BOOK OF), and even Charles thinks it possible that book iv was written at that time in Aramaic. If one writer could make Enoch prophecy in Aramaic, another could; it is by no means certain that book i is pre-Maccabæan; the Aramaic had not been imposed upon the Jews by arrogant enemies, and it continued for many centuries to be their vernacular; and the political and religious reaction was chiefly directed against Greek language, thought, and customs, not against Aramaic, though it may have increased the interest in Hebrew. The linguistic evidence is not equally strong in all of the books and can scarcely be said to be absolutely conclusive anywhere. Yet there can be little doubt that the earliest Enoch book known to us was written in Aramaic; book iv was probably also written in Aramaic. If Jubilees (q.v.) was written in Hebrew, book iii is likely to have been written in the same language. There are indeed some indications that seem to point to a Hebrew original for books iii and v (without the additions). So far as books i, iii, iv, and v are concerned, there is therefore at present a practical agreement between Charles and Schmidt; but in regard to the Parables (book ii) their views still differ. There are numerous peculiarities that can be explained either by a Hebrew or an Aramaic original, but some that seem to require an Aramaic. The question would be practically settled if Schmidt's suggestion that the Ethiopic text of book ii may not have been translated from a Greek version should prove to be correct. He was led to this conclusion by the absence of any signs of acquaintance with the Parables in patristic literature and the remarkable correspondence between the three Ethiopic terms used for "son of man" and three expressions found in the Aramaic, but not in

the Hebrew. He called attention to the startling fact that none of the many teachers in the early Church who quoted the Book of Enoch by name, and no patristic writer showing any familiarity with the Enoch literature, reveals the slightest acquaintance with this particular book, in spite of the fact that its conception of the Messiah, so vastly nearer to Christian ideas than anything else in Jewish literature, would naturally have invited quotation. It is not sufficient to cite the identical expressions in the New Testament. Enoch is quoted only by Jude, and he does not draw upon the Parables; and it is far more difficult to conceive of a Greek version of the Parables being used by several New Testament writers without mention of the work and then totally disappearing, while other parts of the Enoch literature, not thus honored, were preserved and highly prized, than that the present Ethiopic text has here and there received, in the course of transmission, a certain coloring by Christian hands. When Tertullian says that Enoch prophesied concerning the Lord, he probably thought of the passage also quoted by Jude from book i. Charles assumes that book ii was originally written in Hebrew, that there was a Greek version possibly as early as the first century B.C., that in it the Messianic title *ὁ υἱὸς τοῦ ἀνθρώπου* (*ho huios tou anthrōpou*), "the Son of Man," was uniformly used, and that the Ethiopic translation was made by an Aramaic-speaking Jew who, familiar with the Aramaic expressions *bereh de nasha*, *bereh de gabra*, and *bereh de barnasha*, rendered the same Greek title with the Ethiopic expressions exactly corresponding to these Aramaic terms. But an Aramaic-speaking Jew would not have thought of, or understood, these grammatical curiosities by which men attempted to render the New Testament title unless he was a Christian, and, if he was a Christian, he must have had some reason in the text before him for not using everywhere the title uniformly employed in the Ethiopic New Testament. The probability is against the theory of Charles; but only the discovery of the original or of the Greek version, if there was one, can settle the problem, which is of great importance, not only for this book, but for the origin of the title in the New Testament.

As to the date of the different books, there is to-day a general agreement that books i and iv are the earliest, and that book ii is the latest of the five. A difference of opinion, however, exists in reference to the precise dates. While some scholars think that book i is pre-Maccabæan and book iv earlier than 161 B.C., others hold that these books were written in the time of John Hyrcanus (134-104 B.C.). The former base their argument upon the existence of a strongly organized Chasidean party in the beginning of the second century B.C., for which the latter cannot find sufficient evidence (see CHASIDS); and the former interpret the great horn in xc, 9 as referring to Judas Maccabæus, while the latter understand it as referring to John Hyrcanus. Book i may have been written c.120 B.C., book iv c.108 B.C.; book iii is quite generally assumed to have been written c.100 B.C., and book v is likely to be somewhat younger. More radical is the divergence of opinion as regards book ii. The Christian origin of the whole book, once advocated by many students, is scarcely maintained by any

one now. But while some eminent scholars, like Dillmann, Charles, Beer, and Martin, have held that the Parables were written in substantially their present form before 64 B.C., others, like Krieger, Holtzmann, Baldensperger, and Schürer, have assigned them to the age of Herod. The first group looks upon "the kings and the mighty," often mentioned, as the later Hasmonaans and the Sadducees; the second sees in them references to the Roman rulers. The difficulty with the former interpretation is that it is not easy to see how Alexander Jannæus and his Sadducean supporters can be spoken of as "the kings and the mighty ones in the earth" and charged with putting their "faith in the gods they have made with their own hands" (xlii, 7). If the Roman emperors and provincial governors are intended by "the kings and the mighty," the persecutions of the congregations of the righteous would seem to point to the time of Caligula rather than that of Augustus and Tiberius. The reference to the Parthians (lvi, 5) would be possible at any time after their power had been felt in the land as it was in 40-37 B.C.; if *Nero redivivus* is thought of, the passage may be an interpolation. A decisive evaluation of the internal evidence is made extremely difficult by the question as to the integrity of the text, which fairly thrusts itself upon every investigator. Aside from the Noachic interpolations, long recognized, many other additions have been discerned, and at present there is a tendency to look upon the "son of man" passages as coming from another author than the writer who speaks of the Messiah as the "Elect One." There is often as good manuscript authority for "the chosen ones" as "the Chosen One," and it is quite doubtful whether the original work referred to the Messiah rather than to the chosen people. The "son of man" passages are probably all of them later, but they manifestly do not all come from the same hand. Some of them do not go beyond the conception of the Messiah found in IV Esdras and the Syriac Baruch, written in the reign of Domitian, while others, loosely attached to the context, and reminiscent of New Testament phraseology, seem to be of Christian origin. The Parables have evidently been worked over already in the Aramaic original. In its simplest form the book may have been written by a Jewish author in the time of Caius Caligula (37-41 A.D.), interpolated perhaps not long after Nero's death (68 A.D.) by another Jewish writer, gone through Christian hands, suffering some changes, and found its way through Aramaic-speaking Jewish-Christian missionaries to Abyssinia. Having been rendered by these into Ethiopic, the book may have been given its place in the collection because of its value as the second vision that Enoch saw. Finally, some copyist seems to have interpolated here, as in other books, extracts that seemed suitable from an apocalypse of Noah, probably translated from the Greek. This possibility, and the growing conviction on the part of scholars that the Parables have not escaped the usual fate of apocryphal books, serve as a warning against the reliance upon them as *in toto* an expression of pre-Christian Jewish opinion. On the Noachic fragments, see NOAH, BOOK OF.

Bibliography. The Ethiopic text was edited by Laurence (Oxford, 1838). Dillmann (Leipzig, 1851), Flemming (ib., 1902), Charles (Oxford,

1906); the Greek text by Bouriant (Leipzig, 1892, and in facsimile, 1893), Dillmann (ib., 1892), Lods (Paris, 1893), Charles (Oxford, 1893), Radermacher (Leipzig, 1901). There are translations in English by Laurence (Oxford, 1838), Schodde (Andover, Mass., 1892), and Charles (Oxford, 1893; 2d ed., 1912); in German by Hoffmann (Jena, 1833-38), Clemens (Stuttgart, 1850), Dillmann (Leipzig, 1853), Beer in Kautzsch's *Apokryphen und Pseudepigraphen des Alten Testaments* (Leipzig, 1902), Flemming and Radermacher (Leipzig, 1902); in French by Brunet in Migne, *Dictionnaire des Apocryphes* (Paris, 1856); Lods, of the Greek text, chaps. i-xxxii (ib., 1892), Martin (ib., 1906); in Hebrew by Goldschmidt (Berlin, 1892); in Latin by Silvestre de Sacy in *Magasin encyclopédique*, pp. 382 ff. (Paris, 1800, 15 chaps. only), Gröber, in *Prophetæ Veteres Pseudepigraphi* (Stuttgart, 1840), and Székely, in *Bibliotheca Apocrypha* (Freiburg, 1913). Consult also De Sacy, in *Journal des Savans* (Paris, 1822); Murray, *Enoch Restitutus* (London, 1836); Krieger, *Beiträge zur Kritik* (Nürnberg, 1845); Lücke, *Einleitung in die Offenbarung des Johannes* (2d ed., Bonn, 1852); Ewald, *Abhandlung über des äthiopischen Buches Henoch Entstehung* (Göttingen, 1855); Hilgenfeldt, *Die jüdische Apokalypstik* (Jena, 1857); Halévy, in *Journal Asiatique* (Paris, 1867); Tideman, in *Theologisch Tijdschrift* (Leiden, 1875); Drummond, *The Jewish Messiah* (London, 1877); Baldensperger, *Das Selbstbewusstsein Jesu* (3d ed., Strassburg, 1903); Appel, *Die Komposition des äthiopischen Henochbuches* (Gütersloh, 1906); Schmidt, *The Original Language of the Parables of Enoch* (Chicago, 1908); Schürer, *Geschichte des jüdischen Volkes*, iii (4th ed., Leipzig, 1909); Charles, in *Old Testament Apocrypha and Pseudepigrapha* (Oxford, 1913).

Slavonic Enoch. In 1880 Popov published *The Book of the Secrets of Enoch*, from a manuscript written in 1679 in a South Russian dialect; in 1886 Sokolov found in Belgrade an old Slavonic manuscript of the sixteenth century, which is the same recension, generally designated as A. Novaković published in 1884 a Serbian manuscript of the sixteenth century, found at Belgrade, representing a different recension, known as B; of the same type are a manuscript in Vienna of the sixteenth century, collated by Bonwetsch, and a manuscript of the seventeenth century owned by Barsov in Moscow; a number of fragments, some of them as old as the fourteenth century, published by Tichonravov, Pypin, and Popov, also agree substantially with B. The relation between these two recensions has not yet been definitely determined. Charles and Bonwetsch agree in regarding A as more original, and B as an incomplete edition, though admitting many interpolations in A. The difficulty with this view is that B would then by accident, since intention is inconceivable, have left out just those passages and turns of expression that have been relied on to prove that the work was written in Greek by an Alexandrian Jew. Charles indeed maintains that some parts may originally have been written in Hebrew, but deems it impossible to separate these. The two recensions are perhaps most naturally explained if it is supposed that B is the first Slavonic translation, made from a Greek version of a Hebrew or Aramaic original, while A is a later Slavonic translation made

by one who had before him B, which he followed in the main, but also a different Greek manuscript which had been amplified by some Alexandrian copyist. There is nothing in the shorter recension that could not have been written by a Palestinian Jew about the middle of the first century A.D. Neither the silence concerning a Messiah, nor the reference to the world to come without the mention of a resurrection, militates against this conclusion. Christian interpolations have been suggested; but though the form of the Beatitudes and the ethical views here and there remind us of the Gospels, there is nowhere any distinctively Christian conception or expression. The same applies largely to the longer recension as well, which shows some traces of Alexandrian thought; influence of the Christian reasoning in favor of the eighth, i.e., the first, day in Barnabas xv, 4, may, however, be suspected in xxxiii, 1-2. The book was known to Origen. It is important because it gives a description of all the seven heavens, and even more so because it reveals an ethical development in some Jewish circles in Palestine, contemporaneous with, but independent of, Christianity, tending in the same direction. Consult: Morfill and Charles, *The Book of the Secrets of Enoch* (Oxford, 1896); Bonwetsch, *Das slavische Henochbuch* (Berlin, 1896), later than Morfill's, with a full description of the manuscript; Harnack, *Geschichte der altchristlichen Litteratur* (Berlin, 1897); Schürer, *Geschichte des jüdischen Volkes*, iii (4th ed., Leipzig, 1909); Forbes and Charles, *Old Testament Apocrypha and Pseudepigrapha* (Oxford, 1913).

ENOCH ARDEN. A narrative poem by Tennyson (1864). Its hero and title character is a shipwrecked sailor who finally returns home and finds his wife remarried. He leaves her to her new life, peacefully unconscious that her first husband is still alive.

ENOCK, C. REGINALD (1868-). An English mining engineer and traveler. His best-known work is in his books on Latin America, which give excellent summaries of primitive history, conquest, wars for independence, and modern industrial conditions. Among his publications the principal titles are: *The Andes and the Amazon* (1907); *Peru* (1908); *Mexico* (1909); *The Great Pacific Coast* (1910); *Farthest West: Life and Travel in the United States* (1910); *The Secret of the Pacific* (1912); *Republics of Central and Southern America* (1913); *Ecuador* (1914).

ENOMOTO BUIO, ā'nō-mō'tō bōō'yō (1839-1909). A Japanese statesman, born in Tokyo. He was sent in 1860 to study in Europe. In Holland he obtained a solid training in science and naval practice and in 1867 he returned to Japan. After the final triumph of the Mikado in the civil war of 1867-68 Enomoto established in the southern part of the island of Yezo a republic, of which he was elected the President. In 1869 this government was defeated by the Imperial forces, and Enomoto was imprisoned in Tokyo. Released in 1872, in 1874 he was made vice admiral of the navy and was sent as Minister Plenipotentiary to Russia, where he negotiated the treaty for Saghalien. In 1882 he was Minister to China, and in 1885 he was made Viscount. In 1888 he became a member of the Council of State and Minister of Education, in 1891 Minister of Foreign Affairs, and from 1892 to 1896 was Minister of Agriculture and Commerce.

ENOS, ā'nōs (anc. *Ēnus*). The westernmost seaport of European Turkey, situated on a rocky isthmus near the mouth of the Maritza, in the Province of Adrianople, about 80 miles south-southwest of Adrianople and on the border line between Turkey and Bulgaria (Map: Balkan Peninsula, F 4). Its harbor is commodious, but much neglected and too shallow for deep-sea vessels. The trade, formerly of importance, has greatly decreased, Enos having been superseded as an export centre by the adjacent seaport of Dedeağatch (q.v.). The town is the see of a Greek archbishop. Pop. (est.), 7000-8000, principally Greeks. Homer attests the antiquity of Enos by alluding to it in the *Iliad* (iv, 519).

ENRÍQUEZ GÓMEZ, ěn-rĕ'kĕth gō'mĕth, ANTONIO, called in his early days Enrique Enríquez de Paz (1602-?1662). A Spanish dramatist, novelist, and poet, born at Segovia, the son of a baptized Portuguese Jew. He entered the army and had attained the rank of captain, when in 1636 he was obliged to flee to France to escape the Inquisition. In 1645 he dedicated to Louis XIII, whose major-domo he had become, the work entitled *Luis dado de Dios á Anna*. In 1660 he went to Amsterdam, where he afterward openly professed the Jewish faith. He was consequently burned in effigy by the Catholics of Seville. Before leaving Spain Enríquez had already acquired a reputation as a dramatic poet. According to his own statement, he wrote 22 comedies, of which *A lo que obliga el honor* has been regarded as the best. His other writings include: *La culpa del primer peregrino* (Rouen, 1644), a mystic theological poem; *El siglo pitagórico y Vida de don Gregorio Guadaña* (1644), a series of satirical portraits in mingled prose and verse; and *El Samson Nazareno* (Rouen, 1656), an abortive epic. His works will be found in part scattered through vols. xxxiii, xlii, and xlvii of the *Biblioteca de Autores Españoles*. Consult also J. Amador de los Ríos, *Estudios históricos, políticos, y literarios sobre los judíos de España* (Madrid, 1848).

ENROLLMENT. An entry upon an official or public register or record. In English law the term is applied to the registration of certain documents, such as a deed of bargain and sale, and the like, on the rolls of chancery or of the common-law courts, or by the clerk of the peace on the records of the Court of Quarter Sessions. The Statute of Enrollments, enacted by Parliament in the twenty-seventh year of Henry VIII (1536), as an addendum to the more famous Statute of Uses (1535), was a deliberate attempt to prevent the practice, to which the latter statute opened the way, of making secret conveyances of freehold lands by the process known as bargain and sale. It provided that no such conveyance should be valid unless it was enrolled, or registered, within six months of its date, in one of the King's courts of record at Westminster or in the county in which the lands were situated. The manner in which this statute was evaded, by the invention of the method of conveyance called lease and release, is explained in the articles on **BARGAIN AND SALE**; **LEASE AND RELEASE**. See also **CONVEYANCE**; **REGISTRATION**; **RECORDING**.

In the United States the term "enrollment" is employed with reference to vessels engaged in the coasting and home trade, which are enrolled, while those employed in foreign trade are registered; and the words "registration" and "en-

rollment" are used to distinguish the certificates to those two classes of vessels. Enrollment applies only to the vessels engaged in domestic commerce and in voyages along the coast or in inland waters.

ENS. See **ENNS.**

ENSCHEDÉ, ɛn-skā-dě. A town in the Province of Overijssel, Netherlands, situated about 4 miles from the Westphalian frontier and 30 miles east-northeast of Zutphen (Map: Netherlands, E 2). The principal manufactures are cotton goods, thread, iron products, print goods, and electrical machinery. Over half the town was destroyed by fire in 1862, but it has been rebuilt. Pop., 1900, 24,353; 1910, 35,448.

ENSCHEDÉ, ɛn-skā-dā', JOHANNES (1708-80). A Dutch printer. He was born in Haarlem and educated in Leyden. As the head of the printing establishment founded by his father, Isaac Enschedé, he contributed greatly to the art of printing in his day. He introduced the type known as Holland Gothic. The first important specimen of printing types was issued from his establishment in 1768 under the title *Proef van Lettern*. The firm Johannes Enschedé en Zonen still exists in Haarlem.

ENSEMBLE, ɛn'sɛn'bl' (Fr., entirely). All the parts of a thing considered as a whole. Also the total, general effect produced, e.g., by all the figures or objects in a picture or other work of art, by the persons, plot, etc., of a drama or novel, or by the various parts of a musical performance.

ENSENADA, ɛn'sā-nā'pā. A port of Mexico, in the northern district of the Territory of Lower California, of which it is the capital (Map: Mexico, A 2). It is situated on the Bay of Todos los Santos, which affords a rather poor harbor. Its manufactures consist of leather, flour, candy, low-grade shoes, and some vehicles, mainly consumed by local trade. The town is the seat of a United States consul. Pop., 1910, 2170.

EN'SIGN (OF. *ensigne*, *enseigne*, ML. *insigne*, Lat. *insigne*, banner, from *in*, in + *signum*, sign). The national flag. In most foreign navies the man-of-war and merchant ensigns are different. In Great Britain the naval ensign has a white field, the naval reserve ensign a blue field, and the merchant ensign a red field. (See **FLAG**.) Ensign is the title of officers of the United States navy of the lowest commissioned rank. Midshipmen are commissioned as ensigns upon graduation from the Naval Academy. After service of three years as ensigns, all of which must be at sea, officers are promoted to the rank of lieutenant of the junior grade without regard to vacancies. The pay of an ensign is \$1700 per annum with an increase of 10 per cent after five years' service, including time spent at the Naval Academy. The number of ensigns on the active list in 1914 was about 700.

In military usage the title of ensign was formerly applied to the lowest commissioned rank in the British army. It also existed in the Colonial militia of New England and in the Revolutionary army of the United States. Ensigns were charged with the duty of carrying the regimental colors. The colors of a regiment in a sense stood for the regiment itself, embodying its history and always marking its headquarters. Officers and men were alike educated in their traditions and taught to regard them with so much reverence and affection that in return they frequently defended them with the utmost

devotion and sacrifice. Modern strategy and battle dispositions render impossible their further use, the title of ensign having already been abolished in 1871 in the British army and the rank of second lieutenant substituted. See **COLORS, MILITARY AND NAVAL**.

ENSIGN, ɛn'sɪn, ORVILLE HIRAM (1863-). An American electrical and mechanical engineer, born at Ithaca, N. Y., and educated at Cornell University. Between 1882 and 1893 he was employed as a machinist in Ithaca, and in various capacities was with the Schenectady Locomotive Works, the Edison United Company, New York, and the General Electric Company, Schenectady. For several years he was electrical and mechanical engineer of several railway and light companies in the region of Los Angeles, Cal.; in 1897, as superintendent and chief engineer of the Southern California Power Company, he planned and constructed the first long-distance 30,000-volt transmission line, and when this company became a part of the Edison Electric Company of Los Angeles he continued in the same duties until 1904. He then became chief electrical and mechanical engineer, and later chief electrical engineer, of the United States Reclamation Service.

EN'SILAGE. See **SILAGE**.

EN'STATITE (from Gk. *ἐνστάτης*, *enstatēs*, adversary, from *ἐνσταθεῖν*, *enistasthai*, to oppose, from *ἐν*, *en*, in + *ιστάω*, *histanai*, to stand; so called from its refractory nature). A magnesium silicate, crystallizing in the orthorhombic system, but usually occurring in lamellar or fibrous masses, sometimes with a submetallic or bronzelike lustre (*bronsite*). It has a vitreous to pearly lustre and in color is white or light yellow, gray or green. It is a common constituent of igneous rocks and by alteration may form considerable masses of serpentine. It is found in Moravia, Bavaria, the Harz Mountains, the Tirol, and in the United States in Putnam Co., N. Y. The fibrous varieties when cut frequently yield a cat's-eye effect and in consequence have some slight value as gem stones.

ENTABLATURE (OF. *entablature*, from *entabler*, ML. *intabulare*, to construct a table or floor, from Lat. *in*, in + ML. *tabulare*, to floor, from Lat. *tabula*, board). In architecture, especially of the classic and neoclassic styles, the cornice with the horizontal bands or members immediately below it. In Egyptian architecture it consisted of a torus, or roll molding, and a high cavetto cornice crowning the wall, or of an architrave or lintel and the torus and cornice crowning a row of piers or columns. In the classic styles each order had its special entablature, consisting of an architrave or epistyle, frieze, and cornice. (See **ORDERS OF ARCHITECTURE**.) In rare instances one of the two lower members is omitted; thus, in the caryatid porch of the Erechtheum the frieze is wanting, and in certain Renaissance and modern works the architrave is omitted. In Greek buildings, which were usually of one story, the entablature was the crowning feature; in Roman many-storied buildings with superposed

ENTABLATURE.

orders, the entire entablature was repeated over each order, forming decorative bands which expressed clearly the division into stories. In many Roman examples in which columns are engaged in a wall or pier or stand free in front of it, the entablature was made to project out over each column, being carried with less projection over the intervening wall spaces; this is called the "broken entablature." In late Roman work, especially in the provinces, the entablature was sometimes carried in a curve over the top of an arched opening (Spalato, Damascus, Baalbek, etc.). The Byzantine architects continued the use of the entablature of three members, and in Italy, and to some extent in southern France (Provence), it continued to appear in Romanesque architecture, disappearing with the advance of Gothic design. In Italy, however, it persisted through the entire Middle Ages, as on the baptistery and cathedral of Florence. The Renaissance revived the classic practice and types, which have continued in use ever since.

Any combination of horizontal bands and moldings resembling an architrave, frieze, and cornice is called an entablature, so that one may properly speak of the entablature of a pedestal, doorway, or piece of furniture. Consult Ware, *The American Vignola* (Scranton, 1910). See ARCHITRAVE; CORNICE; ORDERS OF ARCHITECTURE.

ENTAIL' (OF., Fr. *entailler*, It. *intagliare*, to cut in, from ML. *intaliare*, to cut in, from Lat. *in*, in + ML. *taliare*, to cut, from Lat. *talea*, cutting, rod). Any settlement or conveyance of an estate of inheritance whereby the legal course of succession is "cut off," one or more of the heirs at law being excluded or postponed, and the settlement of land made upon a particular heir or series of heirs. The first distinct trace of the existence of entails is found in the Roman law. The Greeks, indeed, permitted persons to name successors to their estates and to appoint a substitute who should take the estate on the failure of him first named. The substitute, as appointed, was permitted to succeed on the death of the institute (as he was called) without leaving issue or without alienating the estate. But this limited right fell far short of the power of entailing which has since prevailed in various countries. At Rome, under the later emperors, the practice of settling land upon a series of heirs by means of *fideicommissa* (see FIDEICOMMISSUM) grew up and was sanctioned by the state. This was originally simply a trust reposed in the honor of a friend, to whom the property was conveyed, to carry out the will of the grantor, but, like the trust of English and American law, it ultimately received the sanction of the law and was enforced by the courts. In their early form these *fideicommissa* contained merely a substitution of heirs. But by the later law a much fuller form of settlement was admitted, whereby the estate was protected

from every sort of alienation. It is impossible to doubt that this Roman form must have been adopted by the Scottish lawyers in framing their deeds of entail. There are, however, two points in which the Roman law differed from that which prevailed for many years in Scotland—viz., that the former did not . . . right of primogeniture, and that . . . of the deed was restricted to four generations. For the right of primogeniture, as . . . in deeds of entail, we are indebted to the feudal law. That system did not, in its original form, recognize the right of a holder of land to alienate his feudal benefice. But the right of the eldest son to represent his father, both in the duties and privileges of the fief, if not an original principle of the system, was universally recognized in the days of its greatest influence and extent. For a further treatment, see FEE TAIL. Consult the authorities referred to under REAL PROPERTY.

ENTASIS (Lat., from Gk. *ἐντασις*, distention, from *ἐν*, *en*, in + *τάσις*, *tasis*, a stretching, from *τείνω*, *teinein*, to stretch). Convex curvature applied to the upward taper of a column. In the Greek, Roman, and neoclassic styles the shaft diminishes in diameter upward, usually by about one-sixth of its lower diameter; but this diminution is so designed as to produce a delicately curved instead of a straight profile or outline. Although the curve is convex, at no point is the shaft diameter greater than at the bottom: the shaft nowhere *swells*, and columns made with a swelling outline are not of a truly classic type. In the Greek Doric the entasis begins at the bottom of the shaft; in the Ionic and in the Roman orders the lower third of the shaft is generally cylindrical, the entasis beginning at the top of this portion. Rules for laying out the Roman entasis are found in all the books on the orders of architecture (q.v.). The Greek entasis is more delicate than the Roman, and that of the Parthenon was not discovered until Cockerell's . . . early in the last century; the con . . . curve in these columns 34 feet high amounts to less than half an inch. Consult Goodyear, *Greek Refinements* (New Haven, 1912), and the article "Entasis," in Smith, *A Dictionary of Greek and Roman Antiquities*, vol. i (3d ed., London, 1890).

ENTELLUS MONKEY. See LANGUR.

ENTENTE CORDIALE, *än'tänt' kôr'dyäl'* (Fr., cordial understanding). A term used specifically in international politics to signify a certain cordiality, based either on sentiment or on community of interests, between different countries and statesmen. It is not satisfied by the mere absence of strained relations and the maintenance of ordinary relations of international amity, but suggests a relation bordering on an alliance, though a formal alliance is by no means necessary to create it.

ENTERIC FEVER. See TYPHOID FEVER.
